

Regulation of hepatic miRNAs by hypoosmolarity

Inaugural-Dissertation

zur Erlangung des Doktorgrades
der Mathematisch-Naturwissenschaftlichen Fakultät
der Heinrich-Heine-Universität Düsseldorf

vorgelegt von

Nils Bardeck

aus Essen

Düsseldorf, März 2022

Aus der Klinik für Gastroenterologie, Hepatologie und Infektiologie

der Heinrich-Heine-Universität Düsseldorf

Gedruckt mit der Genehmigung der Mathematisch-Naturwissenschaftlichen Fakultät der
Heinrich-Heine-Universität Düsseldorf

Berichtersteller:

1. Prof. Dr. Stephan vom Dahl

2. Prof. Dr. Holger Gohlke

Tag der mündlichen Prüfung: 09.12.2022

Table of Contents

Table of Contents	II
List of abbreviations.....	IV
Zusammenfassung	VII
Summary	VIII
1. Introduction.....	1
1.1.1 Mechanisms of cell volume control	1
1.1.2 Liver cell hydration	3
1.1.3 Cell hydration modulates cell signaling function	3
1.1.4 Cell swelling and proliferation	5
1.1.5 Proliferation of hepatocytes in liver regeneration	6
1.1.6 Cell hydration affects gene expression	6
1.1.7 Metabolic pathways affected by cell volume	7
1.1.8 Effect of cellular hydration on bile acid secretion	7
1.2 The discovery of microRNAs	8
1.2.1 Biogenesis of miRNAs	9
1.2.2 The canonical pathway	9
1.3 miRNA-mediated gene silencing	10
1.3.1 Translational activation mediated by miRNAs.....	11
1.4 miRNAs in cellular compartments.....	11
1.5 Involvement of microRNAs in osmosensing and osmosignaling	12
1.6 Aim of the thesis	13
2. Materials and Methods	14
2.1 Materials	14
2.1.9 Primers for quantitative <i>real-time</i> PCR.....	17
2.1.10 Primer sequences for molecular cloning	18
2.2 Methods	18
2.2.1 Animal models.....	18
2.2.2 Rat liver perfusion	18
2.2.3 RNA isolation from rat liver tissue and cells.....	19
2.2.4 mRNA and miRNA expression analysis by microarray	19
2.2.5 Cell isolation and culture	20
2.2.6 Overexpression of miR-141-3p in primary rat hepatocytes	20
2.2.7 Partial liver hepatectomy	21

Table of Contents

2.2.8 Mechanical stimulation of isolated primary rat hepatocytes	21
2.2.9 Primer design for polymerase chain reaction (PCR)	22
2.2.10 cDNA synthesis from mRNA.	23
2.2.10 Quantitative real-time PCR	24
2.2.12 Synthesis of cDNA for quantitative miRNA analysis	25
2.2.13 Cloning of <i>Cdk8</i> 3'UTR into pMir(+) promoter vector	26
2.2.14 Validation of miR-141-3p target-genes by Dual-Luciferase® Reporter Assay	28
2.2.15 Online databases and bioinformatic tools	29
2.2.16 Statistics	29
3. Results.....	30
3.1 miRNA and mRNA expression changes in rat livers under hypoosmolarity	30
3.2 Connection of miRNA and mRNA expression changes	33
3.3 miQPCR and qPCR validation of hypoosmotically-regulated miR-141-3p.....	35
3.4 Analysis of miR-141-3p in isolated primary rat hepatocytes.	37
3.5 Overexpression of miR-141-3p in primary rat hepatocytes.....	40
3.6 Validation of <i>Cdk8</i> as a target gene of miR-141-3p	43
3.7 Expression of miR-141-3p and <i>Cdk8</i> mRNA after partial hepatectomy (PHx).....	45
3.7 Mechanical stimulation of isolated primary rat hepatocytes.....	46
3.8 Rat liver perfusions with Src-, Erk-, and p38 ^{MAPK} inhibitors	48
3.9 Rat liver perfusion with colchicine	50
4. Discussion	51
4.1 Hypoosmolarity leads to differential miRNA and mRNA levels.....	51
4.2 Downregulation of downstream target genes of miR-141-3p	54
4.3 Hypoosmolarity leads to miR-141-3p upregulation in primary rat hepatocytes and restoration of cytoskeleton.....	57
4.4 miR-141-3p transfection leads to downregulation of target gene candidates.....	58
4.5 Role of miR-141-3p and <i>Cdk8</i> in liver regeneration.....	58
4.6 Regulation of miR-141-3p is sensitive to mechanical stimulation.....	60
4.7 Src, Erk, and p38 ^{MAPK} signal miR-141-3p regulation.....	61
4.8 Conclusion	63
5. References	65
6. Acknowledgements	88
7. List of Figures	89
8. List of Tables	90
9. List of Publications and Scientific Presentations	91
10. Curriculum vitae.....	91

List of abbreviations

Δp	hydrostatic pressure
$\Delta \pi$	osmotic pressure
3'UTR	three prime untranslated region
5'UTR	five prime untranslated region
ACADL	acyl-CoA dehydrogenase
ACTB	beta actin
AGO	argonaute protein
ANOVA	one-way analysis of variance
ATG5	autophagy related protein 5
ATP	adenosine triphosphate
BCL2	Bcl2 apoptosis regulator
BSEP	bile salt export pump
<i>C. elegans</i>	<i>Caenorhabditis elegans</i>
CAMSAP1	calmodulin regulated spectrin associated protein 1
CAV1	caveolin 1
CCNB2	cyclin b2
CCND1	cyclin d1
CD95	cluster of differentiation 95
CDC25A	cell division cycle 25a
CDK8	cyclin dependent kinase 8
CDKN1A	cyclin dependent kinase inhibitor 1a
CIRCKEAP1	kelch like ech associated protein 1
DGCR8	DiGeorge syndrome critical region 8
DMXL1	dmx like 1
DSTYK	dual serine/threonine and tyrosine protein kinase
DUOXA2	dual oxidase maturation factor 2
EGFR	epidermal growth factor receptor
EML4	emap like 4
EMT	epithelial-to-mesenchymal transition
FAK	adhesion kinase p125 ^{FAK}
FBP1	fructose bisphosphatase 1
FBXW7	f-box and wd repeat domain containing 7
FCS	fetal calf serum
FDR	false discovery rate
FOS	fos proto oncogene
FXR1	fragile x mental retardation related protein 1
GJA1	gap junction protein alpha 1
GO	Gene Ontology enrichment
GUCY2C	guanylate cyclase 2c
GW182	trinucleotide repeat-containing gene 6A protein
HCC	hepatocellular carcinoma
HIF1A	hypoxia inducible factor 1 subunit alpha
HSF1	heat shock transcription factor 1
HSP70	heat shock protein 70
HSPA1A	heat shock protein family a member

List of abbreviations

HSPB1	heat shock protein family b member 1
IL-6	interleukin 6
JNK	c-jun n terminal kinase
LAMC2	laminin subunit gamma 2
L_p	hydraulic conductivity
LPC	liver progenitor cells
LUC7L3	LUC7 like 3 pre mRNA splicing factor
MAP	mitogen activated protein
MAP1LC3B	microtubule-associated protein 1 light chain 3 beta
MAP4K4	mitogen activated protein kinase 4
MIEF1	mitochondrial elongation factor 1
MCS	multiple cloning site
miR-141-3p	mature microRNA-141-3p
MIRISC	microRNA-induced silencing complex
miRNA	microRNA
MREs	microRNA response elements
mRNA	messenger ribonucleic acid
mRNP	messenger ribonucleoproteins
MRP2	multidrug resistance associated protein 2
MSANTD2	MYB/SANT DNA binding domain containing 2
MVB	multivesicular bodies
NAGS	n-acetylglutamate synthase
NFAT5	nuclear factor of activated t cells 5
NF-YA	nuclear transcription factor y subunit alpha
NF κ B	nuclear factor kappa b
NOX	NADPH oxidase
NTCP	sodium/taurocholate co transporting polypeptide
ODC1	ornithine decarboxylase
PEPCK	phosphoenolpyruvate carboxykinase
PHX	partial hepatectomy
PRMT1	protein arginine methyltransferase 1
qPCR	quantitative real-time PCR
RAB30	member ras oncogene family
rER	rough endoplasmic reticulum
RGD	tripeptide Arg-Gly-Asp attachment site
RGS20	regulator of G-protein signaling 20
RISC	RNA-induced silencing complex
ROS	reactive oxygen species
RPM	revolutions per minute
RPS6	ribosomal protein S6
RTASE	reverse transcriptase
RVD	regulatory volume decrease
RVI	regulatory volume increase
SCNN1A	sodium channel epithelial 1 subunit alpha
SEM	standard error of the mean
SG	stress granules
siRNA	small interfering RNA
SLC1A7	solute carrier family 1 member 7
SLC22A5	solute carrier family 22 member 5

List of abbreviations

SLC39A10	solute carrier family 39 member 10
SLC9A3	solute carrier family 9 member A3
SMAD	sma- and mad-related protein
SOCS	suppressors of cytokine signaling
STAT	signal transducer and activator of transcription
SYNE1	nesprin 1
TAT	tyrosine aminotransferase
TFEB	transcription factor EB
TGN	trans-golgi network
TIMP1	timp metalloproteinase inhibitor 1
TNF- α	tumor necrosis factor alpha
TUBB	tubulin
VIM	vimentin
WNT	wingless-type MMTV integration site family
XP1	exportin-1
XPO5	nuclear transporter protein exportin-5
XRN4	5' - 3' exoribonuclease 1
ZEB1	zinc finger e box binding homeobox 1
ZEB2	zinc finger e box binding homeobox 2
ZFP18	zinc finger protein 18
ZMPSTE24	zinc metalloproteinase STE24

Zusammenfassung

Leberzellen sind durch ihre kritische anatomische Lage mit dem Portalgefäßsystem und dem restlichen Blutkreislauf in stetiger Verbindung. Folglich sind sie großen Konzentrationsveränderungen von gelösten Stoffen wie Aminosäuren, Gallensäuren und Glukose ausgesetzt. Die gelösten Stoffe erzeugen einen osmotischen Gradienten und induzieren eine transmembrane Wasserbewegung. Damit das ursprüngliche Zellvolumen wiederhergestellt werden kann, erfolgt eine adaptive Reaktion, welche eine passive Wasserbewegung induziert. Veränderungen des Zellvolumens sind wichtige Regulatoren von Zellfunktionen und der damit einhergehenden Genexpression. Sie können als eine Art Transmitter als Reaktion auf verschiedene Stimuli, wie die durch die Hormone Insulin und Glukagon, wirken. Zellvolumenänderungen durch eine Verschiebung der Osmolarität treten auch bei einer Vielzahl von Krankheiten auf, wie der Leberzirrhose und der hepatischen Enzephalopathie. Der mechanische Stimulus, welcher auf die Leberzellen durch Hypoosmolarität ausgeübt wird, tritt ebenfalls bei regenerativen Prozessen in der Leber auf.

In der Vergangenheit konnte gezeigt werden, dass eine Zellschwellung, welche durch Hypoosmolarität induziert wird, zu einer erhöhten Zellproliferation führt. Mit dem Ziel, eine Beteiligung von microRNA Prozessen zu identifizieren, welche durch Zellschwellung induziert werden, wurden Leberperfusionsen durchgeführt. Anschließend wurden diese über Transkriptomanalysen und quantitativer PCR untersucht. In der vorliegenden Doktorarbeit konnten spezifische Veränderungen auf Transkriptomebene als eine direkte Reaktion auf Hypoosmolarität gezeigt werden. Weiterhin konnte die microRNA miR-141-3p als eine osmotisch sensitive microRNA identifiziert werden. Durch die Bindung an die 3'UTR der mRNA von spezifischen Genen, wie der *Cyclin-abhängigen Kinase 8 (Cdk8)*, übt miR-141-3p einen antagonistischen Effekt auf Prozesse wie die Zellproliferation aus. Eine Untersuchung von isolierten primären Hepatozyten zeigte ebenfalls eine Heraufregulation der miR-141-3p nach einer Zellschwellung. Durch Inhibitor-Perfusionen konnte nachgewiesen werden, dass miR-141-3p über den MAP-Kinase-Weg durch die Kinasen Erk-1/2 und p38^{MAPK} reguliert wird. Weiterhin konnte eine Beteiligung der miR-141-3p und deren Zielgen *Cdk8* an regenerativen Prozessen der Leber nach einer partiellen Hepatektomie nachgewiesen werden.

Die vorgelegte Arbeit weist der microRNA miR-141-3p eine mögliche Schlüsselrolle bei der Zellproliferation zu. Die hier aufgezeigten Befunde legen die Vermutung nahe, dass miR-141-3p durch die Modulierung von spezifischen Zielgenen eine Terminierung von proliferativen Effekten hervorruft, um die Zelle vor einer möglichen Entstehung eines hepatozellulären Karzinoms (HCC) zu bewahren.

Summary

Liver cells are connected to the portal vasculature and the rest of the bloodstream by their critical anatomical location. Consequently, they are exposed to large concentration changes of solutes such as amino acids, bile acids, and glucose. These solutes create an osmotic gradient which induces transmembrane water movement. In order for the original cell volume to be restored, an adaptive response occurs that induces passive water movement. Alterations of cell volume are important regulators of cell function and associated gene expression. They can act as a type of second messenger in response to various stimuli, such as those produced by hormones like insulin and glucagon. Cell volume changes due to a shift in osmolarity also occur in a variety of diseases, such as liver cirrhosis and hepatic encephalopathy.

In the past, it has been shown that cell swelling induced by hypoosmolarity leads to increased cell proliferation. With the aim to identify an involvement of microRNAs in processes induced by hypoosmolarity, liver perfusions were performed and subsequently investigated via transcriptome analyses and quantitative PCR. In the present PhD thesis, specific changes at the transcriptomic level as a direct response to hypoosmolarity were shown. Furthermore, the microRNA miR-141-3p was identified as an osmotically sensitive microRNA. By binding to the 3'UTR of the mRNA of specific genes, such as *cyclin-dependent kinase 8 (Cdk8)*, miR-141-3p exerts an antagonistic effect on processes such as cell proliferation. An examination of isolated primary hepatocytes also showed upregulation of miR-141-3p under hypoosmolarity. Inhibitor perfusions demonstrated that miR-141-3p is regulated via mitogen-activated protein kinases Erk-1/2 and p38^{MAPK}. Furthermore, miR-141-3p and its target gene *Cdk8* were shown to be involved in the regenerative process of the liver after partial hepatectomy was conducted.

Taken together, the present study assigns a possible key role to the microRNA miR-141-3p in cell proliferation. The findings revealed here suggest that miR-141-3p induces termination of proliferative effects by modulating its specific target genes to protect the cell from possible hepatocellular carcinoma (HCC) development.

1. Introduction

The liver forms the main organ for the metabolism in mammalian organisms. Numerous physiological processes take place in the liver, including macronutrient metabolism, immune system support, blood volume regulation and the detoxification of compounds by removing xenobiotics through metabolic conversion and biliary excretion [1,2]. The liver is also a main regulator of metabolic homeostasis, since it is responsible for the synthesis, storage and redistribution of nutrients, carbohydrates, fats and vitamins [2]. The ability of the liver to store glucose in the form of glycogen and to recover glucose back via the gluconeogenic pathway is one critical function which provides the energy for the aforementioned processes [3]. Oxidizing and storing of excess lipids in other tissues, such as adipose, is also an important function which is controlled by the liver [4,5]. The cell types residing in the liver are of different embryological origin and include hepatocytes, which make up 60% to 70% of the liver cell population, and 90% of total liver mass [6]. Non-parenchymal cells, like endothelial cells, Kupffer cells, biliary epithelial cells (cholangiocytes), lymphocytes and hepatic stellate cells account for 25% to 40% of the total liver cell population, or 10% of total liver mass [7]. The second most abundant cell population of the liver represent cholangiocytes, as they form the lining in the lumen of the bile ducts [8]. Hepatic stellate cells constitute a dynamic cell population, which exist in an activated or quiescent state. In their quiescent state, stellate cells store vitamin A in lipid droplets and are located on a basement membrane-like structure in the so called 'space of Disse' [9,10]. Each of these aforementioned cell types have unique functions, which cooperatively regulate hepatic functions. A broad range of metabolic functions are directly affected by cell volume changes, e.g. glycogen synthesis [11–14], glycolysis [15], proteolysis [16–18], glutamine breakdown [19], urea synthesis [19–21] and lipogenesis [14]. Hepatocellular hydration state also affects protein synthesis, whereas cell shrinkage inhibits, but cell swelling stimulates protein synthesis [22,23]. Cell swelling is considered as an anabolic signal, while cell shrinkage leads to a catabolic signal, stimulating protein breakdown under the premise that the proteolytic activity is not already at full capacity [16,24–26]. There is a close relationship between hepatocellular hydration and autophagic proteolysis in the liver, whereas an increase in cellular hydration by 1% inhibits proteolysis by roughly 2% [25,27].

1.1.1 Mechanisms of cell volume control

Cell volume is determined by intracellular osmolarity and extracellular tonicity, whereas changes in cell volume are usually initiated by fluctuation in intracellular or extracellular osmolarity. These changes are always associated with diffusion of water molecules across the

1. Introduction

cell membrane (J_v), which in turn is driven by a hydrostatic (Δp) and osmotic ($\Delta\pi$) pressure gradient.

Both pressure gradients depend on the hydraulic conductivity of the cell membrane (L_p):

$$J_v = L_p(\Delta p - \Delta\pi)$$

Most cells can counteract volume perturbations. This behavior is characterized by a regulatory cell volume decrease (RVD), or a regulatory volume increase (RVI), as shown in Figure 1.1. However, the hydration state of cells controlled by RVD or RVI may not completely reconstitute the original hydration state. Therefore, cells are left in a slightly swollen or shrunken state [28].

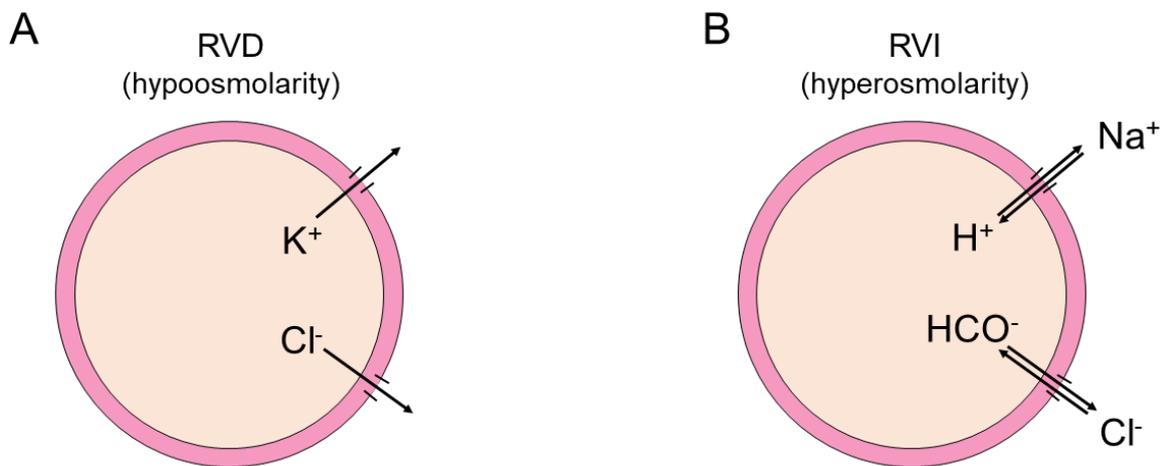

Figure 1.1 Mechanisms underlying regulatory cell volume decrease (RVD) and regulatory cell volume increase (RVI) following hypoosmotic and hyperosmotic exposure in hepatocytes. (A) Mechanism of RVD: activation of both K^+ and Cl^- channels resulting in K^+/Cl^- symport out of the cell. (B) Mechanism of RVI: parallel activation of Na^+/H^+ exchange and Cl^-/HCO_3^- antiport. Activation of RVI results in a net export of H^+ and HCO_3^- ions, while Na^+ and Cl^- are imported. (Modified and adapted from [28]).

Responsible mechanisms for RVD and RVI differ among cell types and species, but generally involve the recruitment of ion transport systems into the plasma membrane [28–30]. RVD in rat liver is mainly accomplished by the release of cellular potassium, chloride and bicarbonate ions into the extracellular space [31–35], followed by an activation of K^+ channels together with anion channels [36]. Rat hepatocytes under the influence of cell swelling open non-selective cation channels, which allow a cellular intake of for instance Ca^{2+} ions [37], that results in an activation of Ca^{2+} -sensitive K^+ channels [38]. However, it is still under debate if hypoosmotic hepatocyte swelling increases intracellular Ca^{2+} ion concentrations [25], since Ca^{2+} -activated K^+ channels are not solely responsible for RVD. In contrast, in human lymphocytes, cell swelling is not associated with an intracellular accumulation of Ca^{2+} ion concentrations [39].

1. Introduction

There are also K^+ channels in isolated hepatocytes which do not require an enrichment of intracellular Ca^{2+} [40], but are rather activated by cell membrane stretching [41].

Under hyperosmotic conditions, RVI is initiated by simultaneous activation of Na^+/H^+ and Cl^-/HCO_3^- exchangers. In an experimental model of perfused rat livers, hyperosmotic exposure leads to a cellular K^+ uptake which leads to RVI [33,35]. Besides cell volume regulation by ionic mechanisms, some cell types release or accumulate organic compounds in response to cell swelling or cell shrinkage. These organic compounds, so-called 'organic osmolytes', do not interfere with protein function even at high intracellular concentrations [42–44], e.g. inositol and sorbitol [45,46], methylamines (betaine and α -glycerophosphocholine [47,48]), and certain amino acids (taurines [49,50]). These osmolytes are able to create osmotic gradients in the extracellular fluid of up to 1000 mmol/L [43].

1.1.2 Liver cell hydration

Changes in ambient osmolarity, increased amino acid uptake, hormone-induced or toxin-induced ion fluxes across the plasma membrane have a direct impact on the liver cell hydration [28,51,52]. The diffusion of water molecules across the cell membrane is largely dictated by the osmotic pressure gradients [53–56], whereas an imbalance of intracellular and extracellular osmolarity is compensated by diffusion of water molecules across cell membranes. These changes in cell hydration, when inside a narrow physiological range, occur within minutes and directly affect protein and carbohydrate metabolism and gene expression. Despite the activity of cellular volume regulation mechanisms, these regulations are not designed to maintain absolute cell volume constancy, but are rather intended to dampen the effect of hazardous cell volume deviations which would result from cumulative substrate uptake [57] or as a result of diseases [58–60]. Hormones, e.g. insulin, are potent modulators of liver cell volume and impact volume-regulatory mechanisms, while creating a strong signal for cellular metabolism and gene expression [15,28]. For instance, insulin can stimulate the mitogen activated protein (MAP) kinase cascade through a tyrosine receptor-activated signaling cascade. Following a series of protein phosphorylation, membrane ion transporters such as Na^+/H^+ antiporter and the basolateral $Na/K-2Cl$ symporter (solute carrier family 12 member 2 (Slc10a2)) are activated which, subsequently, results in hepatocyte swelling as described in section 1.1.1 [61].

1.1.3 Cell hydration modulates cell signaling function

Detection of changes in cell volume (the so called "osmosensing") and how this information is transmitted and finally results in altered hepatocyte function (known as "osmosignaling"), have been in the spotlight of research for many years. In the past, macromolecular crowding

1. Introduction

(meaning the accumulation of proteins) [62,63], stretch-activated ion channels [64], and histidine kinases were investigated, that might act as potential osmosensors [65]. In hepatocytes, $\alpha_5\beta_1$ -integrins were identified as osmosensors [66]. The $\alpha_5\beta_1$ -integrins are predominantly localized in the plasma membrane and are activated in response to hypoosmotic or insulin-induced hepatocyte swelling [67–69]. $\alpha_5\beta_1$ -integrins mediate cell-cell and cell-extracellular matrix interactions. The integrin-mediated activation of downstream MAP kinases can be fully inhibited by the addition of integrin-inhibitory peptides [70]. Subsequent downstream metabolic events, like the stimulation of bile formation or the inhibition of proteolysis, which are otherwise triggered by hypoosmotic cell swelling, remain inactive in presence of integrin-inhibitory peptides. Studies confirmed that these peptides prevent integrins from binding to tripeptide Arg-Gly-Asp attachment sites (RGD) of extracellular matrix proteins, such as fibronectin, laminin, and collagen [71–73]. This impairment prevents the dynamics of integrin/matrix interactions, which are needed for effective osmosensing and the conversion of mechanical force into biochemical signals, called ‘mechanotransduction’ [74]. Downstream osmosignaling involves the activation of the focal adhesion kinase p125^{FAK} (FAK) [75,76], c-Src, the epidermal growth factor receptor (EGFR), and the mitogen-activated protein kinases Erk (Erk-1 and Erk-2) and p38^{MAPK} [66,77,78], as depicted in Figure 1.2. This signaling pathway mediates RVD and inhibits proteolysis, while p38^{MAPK} activation is required for choleresis [66,79–81]. Cell proliferation has also been shown to correlate with an increase in cell volume [68,82]. Hepatocyte shrinkage, however, leads to an accumulation of reactive oxygen species (ROS) and triggers proapoptotic signaling via a short-term activation of the CD95 death receptor as illustrated in Figure 1.2 [28,51]. In hepatocytes, cell shrinkage induced by hyperosmolarity triggers an increase of the intracellular chloride concentration and a volume-regulatory uptake of K⁺, Na⁺, Cl⁻ into the cell [52,83]. Accumulation of chloride ions in the cytosol directly activates the vacuolar H⁺-ATPase, which results in an endosomal acidification [84]. This acidification leads to an activation of acidic sphingomyelinase, paralleled by a ceramide formation which increases the activation of NADPH oxidase (NOX) [85]. As a byproduct of NOX activity, ROS were identified to trigger activation of c-Jun N-terminal kinase (JNK) and the Src family kinase members Fyn and Yes [86,87]. This signaling pathway also induces the proapoptotic microRNA family 15/107 [88]. Cholestasis is triggered by hyperosmotic activation of Fyn due to retrieval of the bile salt export pump (Bsep) and multidrug resistance associated protein 2 (Mrp2) from the canalicular membrane [86], while sodium/taurocholate co-transporting polypeptide (NTCP) is recovered from the sinusoidal membrane [87]. The proapoptotic state of the hepatocyte is triggered by the activation of Yes and JNK and downstream CD95 activation [89,90].

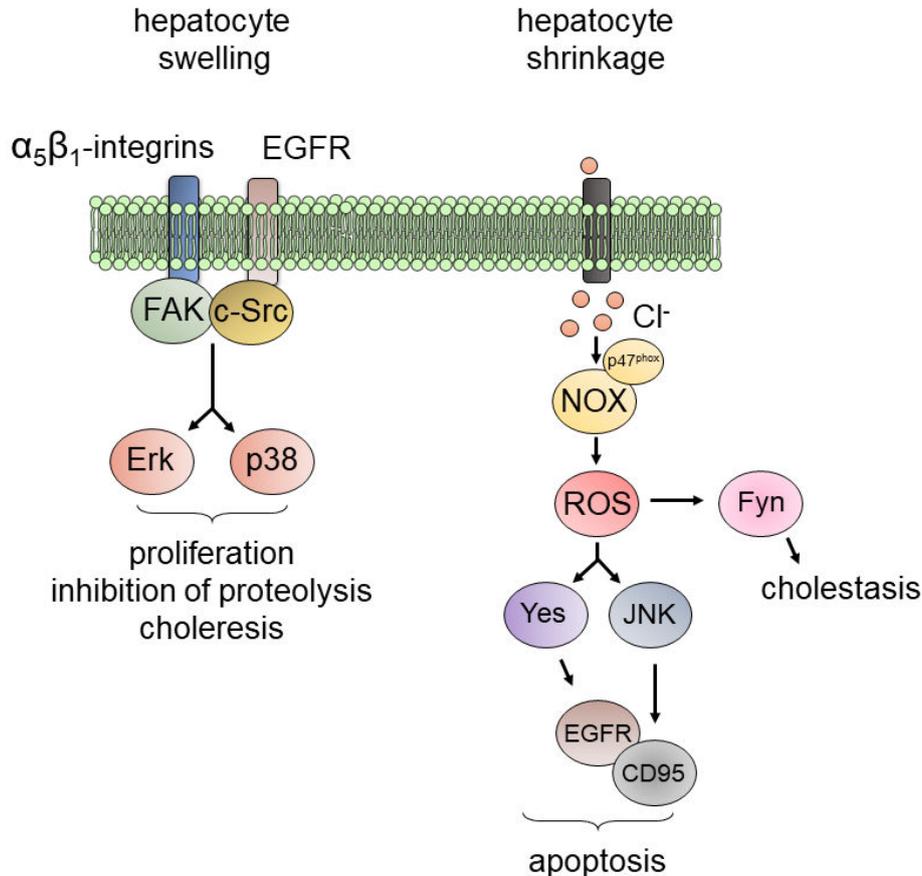

Figure 1.2 Osmosignaling in response to hypoosmotic cell swelling and hyperosmotic cell shrinkage in hepatocytes. (Left) Cell swelling in hepatocytes is sensed by transmembrane adhesion receptor $\alpha_5\beta_1$ -integrins through a mechanical stimulus. Signaling is transduced via focal adhesion kinase (FAK) and c-Src into p38^{MAPK} activation, which results in proliferation, inhibition of proteolysis and choleresis. (Right) Cell shrinkage is accompanied by increase of the intracellular Cl^- ion concentration. Activation of the vacuolar H^+ -ATPase triggers a cytosolic acidification, enabling phosphorylation of p47^{phox}, a regulatory subunit of NADPH oxidase (NOX). This results in the formation of reactive oxygen species (ROS), which triggers JNK and downstream epithelial growth factor receptor (EGFR) activation. Cell death 95 (CD95) tyrosine phosphorylation by EGFR activates the death-inducing signaling complex leading to apoptosis. (Modified from [91,92]).

1.1.4 Cell swelling and proliferation

Osmotic cell swelling is linked to an accelerated cell proliferation [93], whereas hypertonic shrinkage inhibits cell proliferation [94–97]. In fibroblasts, *Ras* oncogene expression is accompanied by accumulation of intracellular Na^+ ions and export of H^+ ions out of the cell which ultimately leads to an increased cell volume [98–100]. This increase in cell volume is related to fluctuations of intracellular Ca^{2+} ion concentrations [101]. These fluctuations in intracellular Ca^{2+} ion concentration cause a transient shrinkage, due to the activation of Ca^{2+} -sensitive potassium channels [102,103].

However, this process is followed by a sustained increase of cellular volume, due to a depolymerization of actin filaments, since the end of actin filaments are modified by

1. Introduction

Ca²⁺-dependent gelsolin complex [101,104,105]. Na⁺/H⁺ ion exchange accelerates *Ras* oncogene expression, which in turn initiates cell proliferation [100,106,107]. However, in certain cases, inhibition of the Na⁺/H⁺ exchanger was not found to impede with cell proliferation, indicating that the activity of ion channels and transporters is not a prerequisite for swelling-induced cell proliferation [108–110]. Erk-1 and Erk-2, are both proteins which are involved in cell cycle regulation and activated by cell swelling [111]. Erk-1 and Erk-2 share a similarity of 84% in their amino acid sequence and also share a functional similarity [112], hence they are usually referred to as Erk-1/2.

1.1.5 Proliferation of hepatocytes in liver regeneration

Adult hepatocytes normally do not undergo cell division but still maintain the ability to proliferate in response injuries or infections. Removal of two thirds of the liver results in the enlargement of the remaining liver until the original liver mass is restored as shown by Higgins and Anderson in 1931 [113]. However, the word ‘regeneration’ can be falsely interpreted, since the severed liver lobes do not grow back, but instead are replaced in a hyperplastic response by the remaining liver cells. Once the original mass of the liver, adjusted and determined by the demands of the organism, is restored, proliferation stops. The three phases of liver regeneration consist of: priming stage, proliferative phase, and termination phase. In rats which were subjected to partial hepatectomy (PHx), the rate of DNA synthesis in hepatocytes is increased after 12 h and peaks around 24 h [114]. During this time point, hepatocytes enter the S phase of the cell cycle, whereas Kupffer and biliary epithelial cells start at around 48 h after PHx. The biggest part of the increase in liver mass occurs 3 days after PHx and is completed after 5 to 7 days [115]. During liver regeneration, liver cells endure both compression and stretching, whereas cell division is accompanied by cell swelling [91,92]. These processes and signal mediations also share the same pathway which are triggered by activation of $\alpha_5\beta_1$ -integrins [69,91,116].

1.1.6 Cell hydration affects gene expression

Cell swelling and shrinkage influence the expression of a broad range of genes. In hepatocytes subjected to hypoosmolarity, genes which are relevant for cell structure like *tubulin* (*Tubb*) and β -*actin* (*Actb*) are upregulated, whereas the *tumor necrosis factor* (*TNF- α*) is downregulated [117–119]. The involvement of genes which participate in the structural integrity of cells, point towards an involvement of the cytoskeleton in the molecular response to cellular hydration [120]. A variety of genes encoding for heat shock proteins, that serve to stabilize other proteins and that counteract the effects of increased extracellular salt concentrations, are upregulated under cell shrinkage, e.g. genes encoding for *heat-shock protein 70* (*Hsp70*) and *heat-shock transcription factor 1* (*Hsf1*) [121–123].

1.1.7 Metabolic pathways affected by cell volume

Hormones can serve as mediators, which trigger volume regulatory mechanisms to exert their sustained effects on cellular metabolism. For example, insulin and glucagon can impact the cellular volume, thereby influence cell metabolism. Insulin has a direct effect on liver cell volume and triggers a variety of metabolic functions, i.e. protein and glycogen synthesis, while protein and glycogen degradation are inhibited [15,66,78]. In perfused rat livers, insulin-induced cell swelling can be counteracted by the addition of glucagon. As a major hormonal regulator of glucose metabolism, glucagon decreases cellular K^+ , Na^+ , and Cl^- ion concentrations by opening responsible ion channels and, thus, leading to cell shrinkage [124,125]. However, glucagon and other Ca^{2+} -mobilizing hormones also act as modulators of mitochondrial matrix volume, whereas cytosolic and mitochondrial water spaces are inversely affected. For example, liver cells exposed to glucagon undergo cell shrinkage but simultaneously have swollen mitochondria [126].

Nutrients were also shown to impact cellular hydration state, resulting in the alteration of protein, glycogen, and lipid metabolism. For instance, addition of glutamine and glycine to rat liver perfusion media resulted in cell swelling to the same extent as under the influence of hypotonic media, whereas both conditions resulted in an inhibition of proteolysis [16]. Other amino acids, e.g. phenylalanine, proline, alanine, and serine also exert an anti-proteolytic effect which is accompanied by cell swelling [127–129]. For example, in rat hepatocytes uptake of L-alanine occurs through a secondary active transport system coupled with Na^+ ions [130]. Cellular accumulation of the Na^+ ions and alanine concentrations result in an osmotic driving force which causes cell swelling [131]. However, macromolecular synthesis and breakdown are not the only processes that are affected by the alteration of cell volume. In hepatocytes, the information on metabolic effects, which originated by modifications of cellular volume, have also been studied extensively [132–135].

1.1.8 Effect of cellular hydration on bile acid secretion

Several cellular functions, such as bile acid secretion, are controlled by the hepatocellular hydration state. Conjugated bile acids are transported across the canalicular membrane by Na^+ -dependent transporters (e.g. sodium-dependent bile salt transporter (Asbt, Slc10a2)) [136,137]. The canalicular excretion is predominantly accomplished by an ATP-dependent transport system and is thought to be the overall rate-controlling step for transcellular bile acid transport. In perfused rat livers, the rate of transcellular taurocholate transport critically depends on the hydration state of the hepatocyte [138,139]. Regardless of whether cellular volume is altered by ambient osmolarity or influenced by amino acid uptake, taurocholate excretion is inhibited by cell shrinkage but stimulated by cell swelling [138]. Here, an increase

of the hepatocellular hydration of 10% roughly doubles the bile salt excretory capacity within minutes [140]. However, this increase is not tied to changes in cellular ATP content, but can be extinguished in the presence of colchicine which induces the disassembly of α -tubulin [24]. This effect ultimately leads to the depolymerization of the microtubule network. This points towards a requirement for intact microtubules and suggests that the microtubule network is required for the interaction between cellular hydration and taurocholate excretion into bile and can be disrupted by colchicine [31,51,141]. Rapid changes in taurocholate secretion can be partially explained by a microtubule-dependent insertion or retrieval of canalicular bile acid molecules into or from the canalicular membrane [31,136,138,141].

1.2 The discovery of microRNAs

As a revolutionary discovery in the field of molecular biology, the first microRNA (miRNA) *lin-4* was discovered in 1993 in *Caenorhabditis elegans* by the groups of Ambros and Ruvkun [142,143]. Several years earlier, *lin-4* gene was already characterized by the Horvitz's lab, where they discovered *lin-4* as one of the genes that regulate temporal development of *C. elegans* larvae [144]. In 1987, Horvitz's lab discovered a mutation in *lin-4*, that had an opposite phenotype to a mutation in another gene, called *lin-14* [145,146]. Ambros and Ruvkun later discovered that *lin-4* is not a protein-coding RNA, but rather a small so called 'non-coding RNA' [147,148]. It was discovered that *lin-14* is downregulated post-transcriptionally through its 3' untranslated region (UTR) and that *lin-4* has a complementary sequence to that of the 3'UTR of *lin-14* mRNA [149]. It was then proposed that *lin-14* is regulated by *lin-4* at the post-transcriptional level [150]. Since then, new miRNAs are still being discovered [151] and have been detected in nearly all animal model systems, while some were also shown to be highly conserved across species [152–154]. Being recognized as regulators of gene expression, miRNAs are short non-coding RNAs, with roughly 22 nucleotides in length. miRNAs are transcribed from DNA sequences into primary miRNAs transcripts (pri-miRNAs), are then processed into precursor miRNAs (pre-miRNAs), and finally into mature miRNAs. In most cases, interaction with the 3'UTR of target mRNAs is established and results in a post-transcriptionally suppressed mRNA [155]. It has also been reported, that interaction of miRNAs occur with other regions, including the 5'UTR, coding sequence and even with gene promoters [156]. Under certain conditions, miRNAs were also shown to activate gene expression [157]. Furthermore, recent studies have suggested that miRNAs are conveyed between different subcellular compartments to control the rate of translation and even transcription [158]. Many studies also detected extracellular miRNAs in biological fluids such as plasma/serum [159,160], cerebrospinal fluid [161], saliva [162], and breast milk [163]. However, the exact functions of extracellular miRNAs are still awaiting further analyses.

1.2.1 Biogenesis of miRNAs

The miRNA biogenesis starts with the synthesis of the transcripts by RNA polymerase II or III [164]. Depending on their genomic position, miRNAs can be classified into intragenic and intergenic miRNAs [165,166]. For example, intragenic miRNAs, embedded within exons or introns of protein coding genes on the same strand, are believed to be co-regulated with their host genes by RNA polymerase II. Intergenic miRNAs, which are located between genes, have their own RNA polymerase II or III promoters. However, recent studies revealed that intragenic and even intronic miRNAs are not always co-transcribed with their host genes [167,168]. Some miRNAs are also co-transcribed from a single, long transcript, called clusters. These clusters may have similar 'seed regions' (between nucleotides 2-8 from the miRNA 5'-end), and in this case they are considered as a family [169].

1.2.2 The canonical pathway

The canonical pathway, as illustrated in Figure 1.3, is the dominant pathway by which miRNAs are processed. The pri-miRNAs are processed into pre-miRNAs by the microprocessor complex. Main components of the microprocessor complex consist of an RNA binding protein DiGeorge Syndrome Critical Region 8 (DGCR8) and a ribonuclease III enzyme, Drosha [170]. DGCR8 is responsible for the recognition of N6-methyladenylated GGAC and other motifs within the pri-miRNA [171], while the pri-miRNA duplex is cleaved by Drosha at the base of the unpaired RNA loop, a secondary structure which constitutes a hairpin [172]. This cleavage results in a 2-nucleotide overhang at the 3'-end of the pre-miRNA which is necessary for the binding to the nuclear transporter protein exportin-5 (XPO5)/RanGTP complex. Once the pre-miRNA is exported out of the nucleus, it is processed by the RNase III endonuclease Dicer in the cytoplasm [170,173,174]. During this process the terminal loop is removed, resulting in a mature miRNA duplex [175]. Depending on the orientation of the mature miRNA strand relative to the position within the pri-miRNA transcript, the name of the mature miRNA is determined. The 5p strand is located near the 5' end of the pri-miRNA hairpin and the 3p strand near the 3' end. Both strands can be recruited into the Argonaute (AGO) family of proteins, which requires the assistance of heat shock proteins such as HSP90 or HSP70, in an ATP-dependent manner [176,177]. The mechanisms behind the selection of the mature miRNA is different among AGO proteins, while the strand which is loaded into AGO is referred to as the 'guide strand'. The unloaded strand, which is called the 'passenger strand', is unwound. AGO2 may cleave passenger strands of miRNAs which contain no mismatches to the guide strands and initiate the degradation of the passenger strand by the cellular machinery. miRNA duplexes with central mismatches or non-AGO2 loaded miRNAs may be unwound and further degraded [164].

1. Introduction

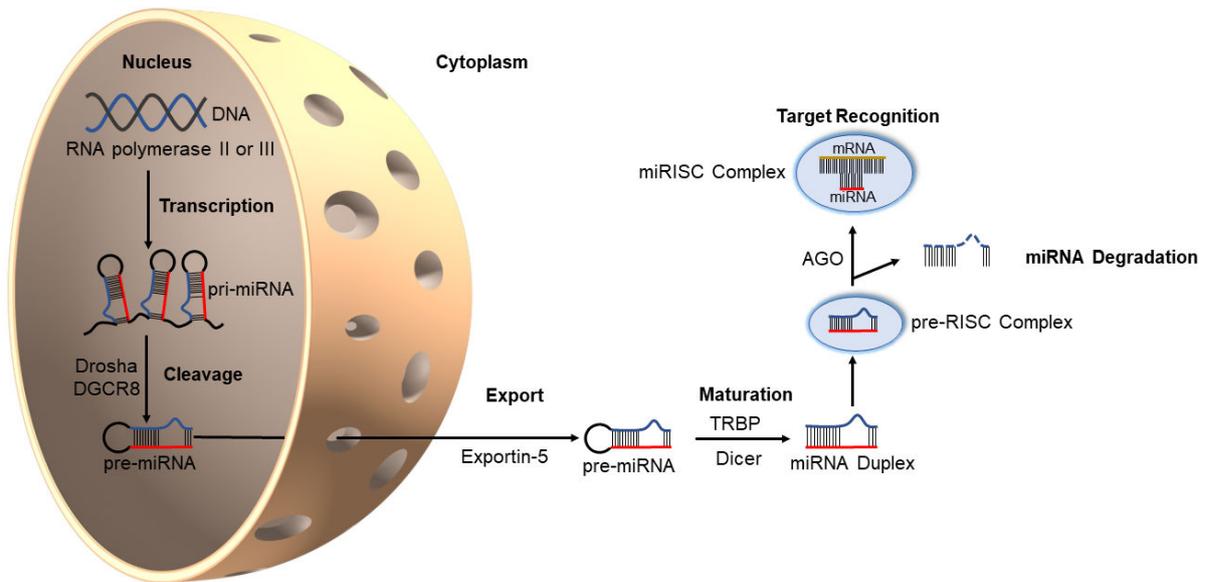

Figure 1.3 MicroRNA biogenesis and mechanisms of action. Canonical miRNA biogenesis starts with the pri-miRNA transcription by RNA polymerase II or III. The microprocessor complex, consisting of Drosha and DGCR8 produces the precursor-miRNA (pre-miRNA) by cleaving the stem sequence of the pri-miRNA. The pre-miRNA is then exported into the cytoplasm via exportin-5 and processed by the RNase Dicer to produce the mature miRNA duplex. Afterwards, the 5p or 3p strands of the mature miRNA duplex may be loaded into Argonaute (AGO) family proteins to form the miRNA-induced silencing complex (miRISC).

1.3 miRNA-mediated gene silencing

The guide strand of the mature miRNA and AGO proteins form the minimal miRNA-induced silencing complex (miRISC) [178]. Due to its interaction with the complementary sequences on target mRNA, the target specificity of miRISC is determined. The target site on the mRNA which is recognized by the miRNA is called miRNA response elements (MREs). In most cases, a functional miRNA-MRE interaction is established by formation of hydrogen bond between the 5' sequence of the miRNA, the so called 'seed region' (between nucleotides 2-8) and the mRNA [179,180]. Aiding the stability, additional pairing at the 3'-end of the miRNA increase the binding capacity of the miRNA target interaction [156]. Depending on the degree of MRE complementarity to the miRNA, a miRISC-mediated translational inhibition with further target mRNA decay or an AGO2-dependent slicing of target mRNA is determined [181]. Target mRNA cleavage is induced by AGO2 endonuclease activity when a nearly complementary miRNA-MRE interaction is present [181]. The remaining fragments are bound to be further degraded by exosomes, a multi-protein complex, or by the activity of 5'-to-3' exonucleases, e.g. XRN4 [182,183]. In animal cells, a multitude of not fully complementary miRNA-MRE interactions were discovered [184]. Usually, the majority of MREs contain central mismatches to their guide miRNA, preventing AGO2 endonuclease activity, but enable the binding of other AGO proteins, e.g. AGO1, AGO3, AGO4 [185]. Here, the formation of the silencing miRISC

1. Introduction

complex is followed by the recruitment of the GW182 family of proteins at the GW182 C-terminal region [186]. GW182 contains multiple glycine-tryptophan (GW)-repeats [187,188] and provides the framework needed for the recruitment of other effector proteins [189], including the poly(A)-deadenylase complexes PAN2-PAN3 and CCR4-NOT [190]. The target mRNA poly(A)-deadenylation is initiated by PAN2-PAN3 and finished by the CCR4-NOT complex. Efficient deadenylation is supported by the interaction between the tryptophan (W)-repeats of GW182 and poly(A)-binding protein C (PABPC) [184]. Decapping proteins such as decapping protein 2 (DCP2) are responsible for the removal of the mRNA cap structure [189], followed by an 5' - 3' degradation by exoribonuclease 1 (XRN1) [191].

1.3.1 Translational activation mediated by miRNAs

While most studies are focussing on the inhibitory effects of miRNAs on their targets, recently, few studies reported that miRNAs may up-regulate the level of target mRNAs under certain circumstances. AGO2 and other proteins related to the miRNA-protein complex (microRNPs) were found to be associated with AU-rich elements (AREs) at 3'UTR, resulting in an enhanced translation [192]. For instance, let-7 and several other miRNAs were associated with AGO2 and Fragile-x-mental retardation related protein 1 (FXR1) to activate translation during cell cycle arrest, but also found to inhibit translational process in proliferating cells [192]. These effects were also observed in quiescent cells such as oocytes [193,194]. Here, translational activation by miRNAs is mediated by AGO2 and FXR1 as cofactor instead of GW182 [193]. During amino acid starvation, it was observed that miRNAs bind to the 5'UTR of mRNAs encoding for ribosomal proteins [195], suggesting that under specific conditions miRNAs are able to mediate translational upregulation.

1.4 miRNAs in cellular compartments

Multiple subcellular compartments have been identified to harbor miRISC and target mRNA, including rough endoplasmic reticulum (rER) [196], the trans-Golgi network (TGN) [197], stress granules (SG) [198], processing (P)-bodies [199], early/late endosomes [197], multivesicular bodies (MVB) [200], lysosomes [200], mitochondria [201,202], and the nucleus [203,204]. Depending on the localization of miRISC-mRNA complexes, cofactors that facilitate miRNA-mediated target regulation are accumulated. These effects result in a spatial enrichment of mRNA and miRISC concentrations promoting efficient post-transcriptional regulation [196]. Early on, P-bodies were identified as possible sites for messenger ribonucleoproteins (mRNP), containing mRNAs which were involved in miRNA-mediated suppressive activity [205]. As cytoplasmic foci, they are depleted of ribosomes [205] and accumulated with components of the enzymatic mRNA degradation machinery, e.g. mRNA decapping proteins, the CCR4-NOT complex, XRN1 and GW182 family proteins [206]. Recent

1. Introduction

studies observed that P-bodies enriched with active miRISC are associated with SYNE1 (nesprin-1) which helps binding Argonaute and other P-bodies components to microtubules [207]. Mutation or interference through small interfering RNA (siRNA) of nesprin-1, leads to disruption and significant decrease of miRNA suppression of target mRNA and P-body formation. Whereas, stabilization of microtubules through Taxol leads to translational inhibition of *hypoxia inducible factor 1 subunit alpha (HIF1A)* mRNA with no mRNA decay, followed by an accumulation of P-bodies [208]. It is still unknown to which degree P-bodies are necessary for efficient miRNA-mediated suppression as mRNA degradation machinery exists diffusely throughout the cytoplasm. It was also discovered that formations of miRISC fuse with polysomes, which are complexes of mRNA with multiple translating ribosomes. These miRISC-polysome formations are found heterogeneously distributed in the cytoplasm or bound to the cytoskeleton [209]. A recent study showed that miRISC formations may be bound to membranous subcellular organelles, such as the rER [196]. The same group also reported that rER-bound mRNA, destined for miRNA-dependent degradation, is processed by deadenylation and degradation inside of endosomes and later may be recycled back into the cytoplasm by miRISC [197].

1.5 Involvement of microRNAs in osmosensing and osmosignaling

Several studies showed that miRNAs also play a role in the modulation of the response to alterations of cellular hydration. Santosa *et al.* demonstrated that miR-15a, miR-15b, and miR-16 levels were significantly upregulated in hyperosmotic perfused rat livers [88]. Known as tumor suppressor miRNAs, miR-15a, miR-15b, and miR-16 are members of the miR-15/107 family and serve key functions for repressing the expression of genes which are involved in cell division and metabolism [210]. Interestingly, miR-15a, miR-15b, and miR-16 are anticipated to regulate apoptosis by the inhibition of the anti-apoptotic genes *Bcl2 apoptosis regulator (Bcl2)* and *cyclin D1 (Ccnd1)*, as their interaction between the 3'UTRs of both *Bcl2* and *Ccnd1* was already confirmed in rat, mouse, and human [211–213]. These data underline the effects of hyperosmolarity in hepatocytes, which are known to induce a ligand-independent CD95 death receptor activation, ultimately leading to apoptosis [90,214,215]. Furthermore, it was shown that miRNAs play a role in the maintenance of osmotic homeostasis by participating in the regulation of osmotic stress in zebrafish [216]. Flynt *et al.* demonstrated that miR-8 family miRNAs modulate the expression of *solute carrier family 9 member A3 (Slc9a3)* mRNA, which regulates Na⁺/H⁺ ion exchange activity [217]. Additionally, miR-666 and miR-708, two miRNAs induced by hyperosmolarity, were identified to regulate the expression of aquaporin-1 expression in mice [218]. As identified by Zhao *et al.*, high salinity induced miR-196g and miR-196o levels which transiently inhibited *nuclear transcription factor Y subunit alpha*

(*NF-YA*). Altogether, these data indicate that miRNAs can act as a crucial stress response and enable a sensitive control of gene expression which is caused by environmental changes in osmolarity.

1.6 Aim of the thesis

The present study was performed to gain further insight on hepatic miRNAs and to clarify their potential physiological role in liver homeostasis, tissue development, and regeneration. For this purpose, the role and involvement of miRNAs and their potential target gene candidates were investigated in perfused rat livers under hypoosmotic conditions to further elucidate the participation of miRNAs in osmosensing and osmosignaling. Previously, it was shown that hyperosmotic exposure leads to an upregulation of members of the proapoptotic miR-15/107 family and subsequently to a downregulation of anti-apoptotic genes in perfused rat liver [88]. Therefore, for this study hypoosmotic perfused rat livers were investigated via Affymetrix gene chip analysis. Genome-wide transcriptomic data sets were screened for dysregulated mRNAs and based on these results, target prediction analysis was conducted to identify potential upstream miRNA regulators. Potential interaction of miRNAs with mRNAs, for which binding motifs on dysregulated mRNAs could be identified, were validated by qPCR. Selected mRNAs were further evaluated by stimulation experiments using isolated primary rat hepatocytes transfected with specific miRNA mimic to test the responsiveness of mRNAs to miRNA overexpression. To address the involvement of miRNAs in the osmosignaling cascade, inhibitor studies were performed. Altogether this thesis aimed to provide new insights into the role of miRNAs and their target mRNAs in osmosignaling under hypoosmotic exposure to the liver.

2. Materials and Methods

In the following sections the materials and methods used for the experiments presented in this thesis are listed and explained. Reagents and chemicals that were used in the work for this thesis are listed in the following sections, e.g. enzymes (Table 2.1.1), miRNA mimics and transfection reagents (Table 2.1.2), cell culture media and supplements (Table 2.1.4), bacteria and plasmids (Table 2.1.6). Standard laboratory chemicals were purchased from the companies Carl Roth (Karlsruhe, Germany), Thermo Fisher Scientific (Schwerte, Germany), Merck (Darmstadt, Germany), Biomol (Hamburg, Germany), or J.T. Baker (Deventer, Netherlands), unless otherwise stated. Cell culture dishes were obtained from Eppendorf (Hamburg, Germany) or Thermo Fisher Scientific (Schwerte, Germany). Sequences for primer used in qPCR and molecular cloning are given in Table 2.1.8, Table 2.1.9 and Table 2.1.10.

2.2 Methods

2.2.1 Animal models

This study and all experimental protocols were approved by the local authorities and the methods were carried out in accordance with the guidelines of the Institutional Animal Care and Use Committee of the University Hospital Düsseldorf. Techniques that involve living animals were approved by local officials (LANUV, Landesamt für Natur, Umwelt- und Verbraucherschutz, Recklinghausen, Nordrhein-Westfalen, AZ 84-02.04.2015.A287 and AZ 9.93.2.10.34.07.163) and all animals received care according to the German animal welfare act by indicated persons (see below).

2.2.2 Rat liver perfusion

Male Wistar rats with a body weight of 160 -180 g were anesthetized with 0.1 mL xylazin (Rompun® - 2%) and 0.4 mL ketamine (Ketavet® - 100 mg/mL) by intraperitoneal injection. A dose of 50 U of heparin was injected intravenously in the femoral vein of the hind leg to prevent clotting during the preparation. The vena cava inferior, the hepatic portal vein and the splenic vein were fixed by loose ligatures and a small incision was made, roughly the size at one third of the portal vein was made with microscissors, to insert a small cannula. After insertion of the cannula, the loose ligatures were tied up and the liver was flushed by perfusion medium (Table 2.1.7) with an estimated flow rate of 4 mL/min per g liver weight. To prevent the liver from overflow-induced swelling the abdominal aorta and vena cava were cut through to create a

2. Materials and Methods

drainage via the suprahepatic inferior caval vein right below the ligature, while the ligature of the intrahepatic vena cava inferior was closed tightly. A cannula was placed into the suprahepatic part of the vena cava via the right atrium, so the flow was drained via the suprahepatic inferior caval vein. After preparation of the liver, the system was preperfused for an initial 20 min with perfusion medium. Afterwards, the perfusion medium was either continued with normoosmotic (305 mosm/L) medium or replaced by hypoosmotic perfusion medium (225 mosm/L). Hypoosmotic perfusion medium was prepared by lowering the NaCl concentration of the Krebs-Henseleit buffer to 75 mM. For inhibitor studies, addition of inhibitors to the influent perfusate was performed by dissolution of the compounds in Krebs-Henseleit buffer. Following the preperfusion, normoosmotic medium or hypoosmotic medium was supplemented with 500 nM PD098059 (Calbiochem, Darmstadt, Germany), 250 nM PP-2 (Calbiochem, Darmstadt, Germany), 250 nM PD169316 (Santa Cruz Biotechnology, Heidelberg, Germany) or 500 nM colchicine (Thermo Fisher Scientific, Darmstadt, Germany), respectively. Over a time course of up to 180 min, liver tissue was dissected in a fractionated manner and snap frozen in liquid nitrogen.

2.2.3 RNA isolation from rat liver tissue and cells

Total RNA from liver tissue and primary rat hepatocytes was isolated by phenol/chloroform extraction, followed by spin column clean up. For this purpose, snap frozen liver tissue was mortarized and lysed by addition of 1 mL Qiazol Lysis Reagent (79306, Qiagen) for 3 min by constant vortexing. For RNA isolation from cultured primary rat hepatocytes, cells were washed and rinsed with PBS (Pan Biotech) and exposed to 800 μ L of Qiazol Lysis Reagent for 3 min. Afterwards, 600 μ L of Qiazol was transferred into clean reaction tubes. To separate and extract the RNA from protein and genomic DNA 200 μ L of chloroform were added. Following a short vortex procedure, the samples were centrifuged at 10.000 g for 10 min at 4 °C. Afterwards, the aqueous phase containing the RNA was separated and transferred into clean reaction tubes. By adding 1.5x volumes of 100% ethanol the RNA was precipitated, and RNA purification was performed using the miRNeasy Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. The RNA amounts and quality were measured photometrically by using the DropSense16 spectrometer (Trinean, Gentbrugge, Belgium).

2.2.4 mRNA and miRNA expression analysis by microarray

The extracted and purified RNA samples from rat liver perfusion tissue were sent to the Biologisch-Medizinisches Forschungszentrum (BMFZ) of the Heinrich Heine University in Düsseldorf for transcriptome analysis by gene expression microarray (Affymetrix Rat GeneChip 1.0 ST) and miRNA expression microarray (Rat GeneChip™ miRNA 4.0 Array and Flashtag™ Biotin HSR Labeling, Thermo Fisher Scientific). For this purpose, RNA samples

2. Materials and Methods

from normoosmotic and hypoosmotic condition of time points $t= 0'$ and $t= 180'$ were prepared from 4 independent experiments. The array data were processed by *Transcriptome Analysis Console 4.0* (Thermo Fisher Scientific).

2.2.5 Cell isolation and culture

Primary rat hepatocytes were kindly isolated by Vanessa Herbertz and Nicole Eichhorst. For this, male Wistar rats with a body weight of approximately 200 g were used for isolation of hepatocytes by utilizing a collagenase perfusion technique in an adapted version as described by Meijer *et al.* [219]. Isolated rat hepatocytes were plated on collagen-coated culture plates (Falcon, New York, USA) and maintained in an atmosphere of 5% CO₂ at 37 °C in Krebs-Henseleit medium (Table 2.1.7) supplemented with 6 mM glucose for 4 h. After the initial incubation, medium was removed, and cells were washed with PBS (Pan Biotech) and cultured in William's E Medium supplemented with 5 mM L-glutamine, 100 U/mL penicillin, 0.1 mg/mL streptomycin, 100 nM dexamethasone, 100 nM insulin, and 10% FCS (Table 2.1.7) for 24 h. Normoosmotic (305 mosm/L) and hypoosmotic cell culture media (225 mosm/L) were generated by addition of raffinose to NaCl-free Williams's E culturing media (Table 2.1.7). The adjusted osmolarity was verified using an Osmomat 3000 (Gonotec, Berlin, Germany). Primary rat hepatocytes were either treated with normoosmotic or hypoosmotic medium for 30 min up to 24 h.

Cell swelling was verified microscopically after 5 min and 3 h of hypoosmotic exposure. For this purpose, cell nucleus diameters of isolated primary hepatocytes were measured and analyzed using the software tools of *cellSens Dimensions* (version 1.16, Olympus, Tokyo, Japan). Images were acquired using an Olympus IX 50 microscope equipped with a DP71 camera (Olympus, Tokyo, Japan). For RNA isolation, cells were treated as described in section 2.2.3.

Human embryonic kidney 293 (HEK293) cells were generously provided by Prof. Dr. Verena Keitel (Clinic of Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany). Primary rat hepatocytes were cultured in William's Medium E (Table 2.1.7), while HEK293 were maintained in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% (v/v) FCS, respectively. HEK293 cell line was grown in sterile T75 cell culture flasks (Cellstar®, Greiner Bio-One GmbH), while primary rat hepatocytes were plated on collagen-coated culture plates at 37 °C in a humidified atmosphere containing 5% CO₂.

2.2.6 Overexpression of miR-141-3p in primary rat hepatocytes

Hepatocytes were isolated from male Wistar rats as described in section 2.2.5. Primary rat hepatocytes were transfected with miR-141-3p mimic (Ambion pre-miR™-141-3p miRNA

2. Materials and Methods

precursor, Thermo Fisher Scientific) using the transfection reagent Lipofectamin™ RNAiMAX (Thermo Fisher Scientific). At approximately 80% confluency, cells were transfected according to the manufacturer's instructions. Cells were washed and rinsed with PBS (Pan Biotech) and kept in 5 mL FCS-free cell culture medium. Transfection was performed with 25 pmoles miR-141-3p mimic per well. The miRNA mimic was diluted in 125 μ L OPTI-MEM. The transfection reagent (7.5 μ L per well) was first diluted in 125 μ L OPTI-MEM and then transferred to the diluted miRNA mimic. After an incubation time of 5 min at room temperature (RT), 250 μ L transfection solution were pipetted dropwise on top of the cells. Five hours after the transfection, cell culture medium was replaced by fresh DMEM/ Ham's F-12 containing FCS and cells were harvested 24 or 48 h post transfection. The RNA was isolated as described in section 2.2.3.

2.2.7 Partial liver hepatectomy

A surgical removal of the median and left lateral liver lobe (about 70% of the liver) was conducted with 8 - 10 weeks old male Wistar rats, weighing approximately 250 g body weight, as described by Higgins *et al.* [113]. Samples were collected for two weeks during regeneration. The animals were sacrificed and liver tissue samples were taken in a fractionated manner after the livers had been perfused with physiologic buffer as described by Kordes *et al.* [220]. RNA isolation, qPCR and miQPCR were performed (n=3-6 per indicated time point). The animal experiments were approved by the Landesamt für Natur, Umwelt und Verbraucherschutz (Recklinghausen, Germany; AZ 9.93.2.10.34.07.163) and carried out by Dr. Claus Kordes and Dr. Iris Sawitzka (Clinic of Gastroenterology, Hepatology and Infectious Diseases, Heinrich Heine University Düsseldorf).

2.2.8 Mechanical stimulation of isolated primary rat hepatocytes

Freshly isolated primary rat hepatocytes (Section 2.2.5) were seeded on sterile silicon stretch chambers (STB-100, STREX, San Diego, USA) precoated with Speed Coating Solution (Pelobiotech GmbH, Planegg, Germany). After 24 h, culture supernatant was aspirated, and 1 mL of fresh William's E medium was added. Stretch chambers were elongated by about 30% for up to 3 h or remained unstretched as a control (Fig. 2.1).

Stretching of the cell nucleus was monitored microscopically using an Olympus IX 50 microscope equipped with a DP71 camera and the extent of stretching was calculated by measuring the diameter of the cell nucleus in the direction of elongation, using the software *cellSens Dimensions*. For RNA isolation, cell culture medium was removed, and cells were washed with PBS (Pan Biotech). Using a sterile cell scraper, cells were detached in and transferred into a clean reaction tube, followed by a centrifugation step at 10.000 g for 5 min at 4 °C. The supernatant was discarded, and pelleted cells were lysed by addition of 500 μ L of

Qiazol Lysis Reagent for 3 min. Phenol/chloroform extraction was performed as described in section 2.2.3.

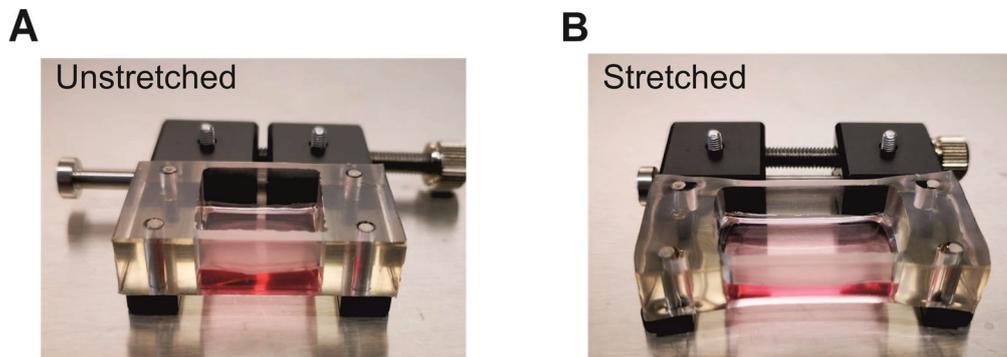

Figure 2.1 Images of cell stretch chambers in their unstretched or stretched state. STB-100 silicone stretch chambers in their unstretched (**A**) and stretched (**B**) state. Cell stretching is conducted by screwing in a bolt in the back of the metal frame.

2.2.9 Primer design for polymerase chain reaction (PCR)

Oligonucleotide primers were designed for PCR amplification of miR-141-3p target gene 3'UTR using genomic sequences obtained from Ensembl Genome Browser (v93 www.ensembl.org/index.html). Melting temperatures for mRNA and miRNA primers were calculated by use of the tool *Oligo Analyzer* 1.1.2 (www.genelink.com/tools/gl-oe.asp). For cloning procedures with the In-Fusion Cloning system, the Cloning Primer Design Tool of Takara Bio Europe (www.takarabio.com/learning-centers/cloning/primer-design-and-other-tools) was used.

The design and assessment of mRNA primers for qPCR was performed by the Roche ProbeLibrary (lifescience.roche.com/en_de/brands/universal-probe-library.html#assay-design-center) with respect to their secondary structure, possible self-dimerization and primer duplexes. The miRNA sequences were obtained from www.mirbase.org (Version 22.1, release October 2018). The oligonucleotides were purchased from Eurofins MWG Synthesis GmbH (Ebersberg, Germany) or Eurogentec Deutschland GmbH (Cologne, Germany).

2.2.10 cDNA synthesis from mRNA.

For mRNA analysis, total RNA from tissue samples and cells was purified (miRNeasy Mini Kit, Qiagen), measured with DropSense16 micro-volume spectrophotometer (2.2.3), and finally taken for cDNA synthesis using the Revert Aid H Minus First Strand cDNA Synthesis Kit (K1632, Thermo Fisher Scientific). For this purpose, 1 μg total RNA in a volume of 20 μL reaction buffer was used according to manufacturer's recommendations using the reaction mixture indicated in the Table 2.2.1:

Table 2.2.1 Reaction mixture for cDNA synthesis

Components	Volumes [μL]
5x Reaction Buffer	4.0
RiboLock RNase Inhibitor (20 U/ μL)	1.0
dNTP Mix (10 mM)	2.0
RevertAid H Minus Transcriptase (200 U/ μL)	1.0
Random Primer (0.2 $\mu\text{g}/\mu\text{L}$)	1.0
OligoDT (0.5 $\mu\text{g}/\mu\text{L}$)	1.0
RNA (1 $\mu\text{g}/\mu\text{L}$)	1.0
Nuclease-free water	9.0
Total reaction volume	20.0

The cDNA was synthesized using the reaction mixture displayed in Table 2.2.1 in a thermal cycler at 65 $^{\circ}\text{C}$ for 5 min, 25 $^{\circ}\text{C}$ for 15 min, and 42 $^{\circ}\text{C}$ for 60 min, followed by heat inactivation at 70 $^{\circ}\text{C}$ for 15 min. Synthesized cDNA was diluted to 1 ng/ μL with nuclease free water and used as template for qPCR.

2.2.10 Quantitative real-time PCR

Quantitative PCR (qPCR) was performed in a qTower³ (Analytik Jena AG, Jena, Germany) with Takyon™ qPCR Mastermix (UF-NSMT-B0710, Eurogentec) using the reaction mixture indicated in the Table 2.2.2:

Table 2.2.2 Reaction mixture for qPCR of mRNA

Components	Volumes [μL]
2x Takyon™ qPCR Mastermix	7.5
Forward primer (10 μM)	2.1
Reverse primer (10 μM)	2.1
cDNA (1 ng/ μL)	2.5
Nuclease-free water	0.8
Total reaction volume	15.0

To analyze each gene of interest, one master mix containing 2x Takyon™ qPCR Mastermix, nuclease-free water and the gene-specific primers was mixed and 12.5 μL of Master Mix were transferred in appropriate 96-well plates (4titude® Ltd, Berlin, Germany). Next, 2.5 μL (2.5 ng) of the respective cDNA was added, whereby each sample was measured in at least two technical replicates. qPCR was performed using the settings depicted in Table 2.2.3:

Table 2.2.3 qPCR program for relative quantification of mRNA

Step	Temperature [$^{\circ}\text{C}$]	Time [s]	Cycles
Heat-activation	95	300	} x45
Denaturation	95	15	
Elongation	72	20	
Melting curve analysis			1x

The melting curve was assessed between 60 $^{\circ}\text{C}$ to 95 $^{\circ}\text{C}$ with a temperature increase of 1 $^{\circ}\text{C}$ per 15 seconds. For relative mRNA quantifications, amplifications curves were analyzed using qPCRsoft 3.2 (Analytik Jena) and a signal intensity threshold within the linear range was set. The threshold cycles (C_t -values) were exported and mRNA quantities were calculated by utilizing *qBase* software v 1.3.5 [221] based on the delta-delta C_t ($\Delta\Delta C_t$) method [222]. The raw data were normalized to the C_t values of the reference gene ribosomal protein S6 (*Rps6*). Statistical analysis was conducted by unpaired student's t-test or one-way analysis of variance (ANOVA) with a significance level of $p < 0.05$ as appropriate.

2.2.12 Synthesis of cDNA for quantitative miRNA analysis

In order to calculate the relative quantity of miRNAs in liver tissue and cells, miQPCR [223] was performed. Due to their short length and a lack of a poly(A) tail, miRNAs require a method which utilizes the activity of T4 RNA Ligase, to uniformly elongate the 3'-ends of small RNAs to a short oligonucleotide adaptor, called miLINKER. Next, PrimeScript™ RTase and reverse-transcription primer (mQ-RT) that specifically hybridizes to the miLINKER adaptor sequence are used to reverse-transcribe the elongated RNA sequences. This method allows for a quantification of various miRNAs of interest, without the need to specifically generate individual cDNAs for each miRNA of interest. The miQPCR was performed in PTC-200 thermal cyclers (MJ research) with 10 ng of diluted RNA and 6 µL of elongation mix (Table 2.2.4), incubated at 25 °C for 30 min and afterwards cooled down to 10 °C. The elongated RNA samples were mixed with 7 µL cDNA Mix 1 (Table 2.2.4) and heated up to 85 °C for 2 min to allow mQ-RT primer annealing. Afterwards, the samples were cooled down to 46 °C, and 5 µL of cDNA Mix 2 (Table 2.2.4) were added. Samples were incubated at 46 °C for 30 min, to complete the first strand reverse transcription. In the final step, samples were heat-inactivated at 85 °C for 2 min and cooled down to 10 °C. A working cDNA stock solution (0.05 ng/µL) was created by diluting to a total volume of 200 µL with nuclease-free water.

Table 2.2.4 Composition of master mixes required for cDNA synthesis by miQPCR (Benes *et al.* 2015)

Components	Volumes [µL]
1) Elongation Mix	
10x T4 Rnl2 Buffer (New England BioLabs)	0.90
MgCl ₂ (450 mM)	0.10
PEG 8000 (50%)	3.10
miLINKER (5 mM)	0.10
RNase inhibitor (40 U/µL, Roche)	0.10
Truncated T4 RNA Ligase (K227Q) (New England BioLabs)	0.20
Nuclease-free water	3.10
2) cDNA Mix 2	
dNTPs (10 mM)	0.05
mQ-RT primer (10 mM)	0.25
Nuclease-free water	7.00
3) cDNA Mix 3	
5x RT Buffer (Takara Bio Europe)	4.40
PrimeScript™ RTase (Takara Bio Europe)	0.14
Nuclease-free water	0.85

2. Materials and Methods

Relative miRNA quantification was then carried out by qPCR with miRNA-specific forward primers and the universal reverse primer Upm2A. The qPCR assays for miRNAs were typically conducted with 2.5 μL cDNA (i.e. 125 pg cDNA) in a total volume of 15 μL as follows:

Table 2.2.5 Reaction mixture for qPCR quantification of miRNAs

Components	Volumes [μL]
2x Takyon™ qPCR Mastermix	7.5
Forward primer (10 μM)	2.1
Reverse primer (10 μM)	2.1
cDNA (50 pg/ μL)	2.5
Nuclease-free water	0.8
Total reaction volume	15.0

A Master mix containing miRNA-specific, universal Upm2A primer, 2x Takyon™ qPCR Mastermix and nuclease-free water was prepared and aliquoted into a 96-well plate together with 2.5 μL of cDNA as described earlier (Section 2.2.9). All samples were measured in at least two technical replicates and qPCR was carried out with the following protocol:

Table 2.2.6 qPCR program for relative quantification of miRNAs

Step	Temperature [$^{\circ}\text{C}$]	Time [s]	Cycles
Heat-activation	95	300	} x50
Denaturation	95	10	
Elongation	60	35	
Melting curve analysis			1x

The melting curve was assessed between 60 $^{\circ}\text{C}$ and 95 $^{\circ}\text{C}$ with a temperature gradient of 1 $^{\circ}\text{C}$ per 15 seconds. Data were analyzed using *qPCRsoft* 3.2 and *qBase* 1.3.5 [221] as described earlier (Section 2.2.11).

2.2.13 Cloning of *Cdk8* 3'UTR into pMir(+) promoter vector

The full length of the rat *Cdk8* 3'UTR was cloned into pMir(+) *Firefly* luciferase plasmid, which derived from pGL3 promoter vector (Promega), as described by Castoldi *et al.* [224] utilizing the In-Fusion Cloning Plus system (Takara Bio Europe). The desired sequence was analyzed, using the In-Fusion Cloning Primer Design Tool, which generates primers that allow the amplification of the 3'UTR with homologous termini to the linearized target vectors (Table 2.1.10). As shown in Table 2.1.10, sequence-specific primers were designed with a *NheI* recognition site at the 5'-end, serving as a forward primer, and a *SacI* recognition site at the 5'-end of the reverse primer, which allowed for the site-directed insertion of the desired

2. Materials and Methods

sequence between the NheI and SacI recognition sites within the multiple-cloning site (MCS) of the reporter plasmids. By switching of the NheI and the SacI recognition sites in forward and reverse directions, two plasmids were generated, one with the 3'UTR in its original orientation (+) and the other with the 3'UTR in antisense orientation (-), used as a control vector.

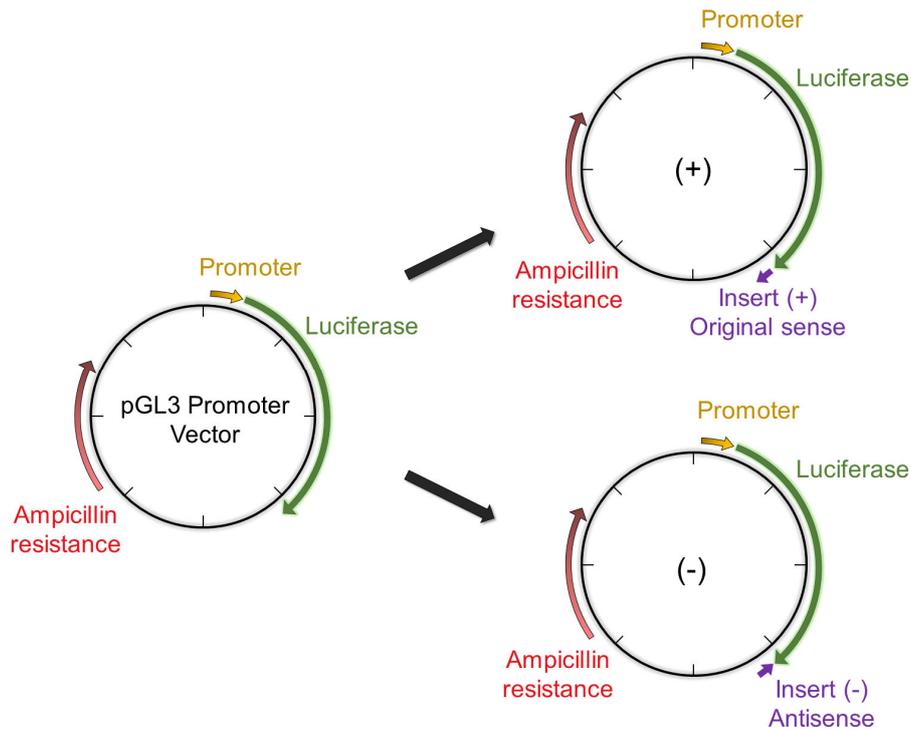

Figure 2.2 Cloning of pMir(+) *Firefly* luciferase plasmid for miR-141-3p target gene validation. Schematic illustration of the generation of two plasmids, one with the insert in its original sense orientation and the other with the insert in its antisense orientation, serving as a negative control.

Amplification of the desired sequence was performed via PCR using a total of 30 ng genomic rat DNA (gDNA) serving as template using CloneAmp HiFi PCR Premix (Takara Bio Europe) according to the manufacturer's instructions. The amplified PCR product was purified with QIAquick PCR Purification Kit (Qiagen). pMir(+) *Firefly* luciferase plasmid was linearized by digestion with 40 U of the restriction enzymes NheI-HF and SacI-HF in 1x CutSmart buffer (New England BioLabs) at 37 °C overnight. Vector and amplified inserts were quantified using DropSense16 spectrometer as described above (Section 2.2.3). For the fusion of vector and insert in a total volume of 10 µL, a total of 50 ng linearized pMir(+) *Firefly* luciferase plasmid and a 2-fold molecular excess of inserts were used together with 1x In-Fusion HD Enzyme Premix. The reaction was performed at 50 °C for 15 min and terminated by cooling on ice. Out of 10 µL reaction mixture, an aliquot of 2.5 µL was transformed in Stellar™ Competent Cells according to the manufacturer's instructions. Transformed bacteria suspensions were plated

2. Materials and Methods

out on LB-agar plates, supplemented with 100 µg/mL ampicillin (Sigma Aldrich), and bacteria were incubated overnight at 37 °C. Bacterial colonies were picked using a sterile pipet tip and inoculated into 2 mL for small-scale or into 50 mL of ampicillin-containing LB-medium for large-scale plasmid preparation. The isolation and preparation of plasmid DNA was conducted with the use of Fast-n-Easy Plasmid Mini-Prep Kit (Qiagen) for small-scale and QIAGEN Plasmid Midi Kit (Qiagen) for large-scale preparation according to the manufacturer's protocol. The recombinant plasmids were sequenced by the Genomics and Transcriptomics Laboratory (GTL) at the Heinrich Heine University (Düsseldorf) using Sanger-Sequencing technique.

2.2.14 Validation of miR-141-3p target-genes by Dual-Luciferase[®] Reporter Assay

To validate the binding site of miR-141-3p onto the *Cdk8* 3'UTR, which was cloned into luciferase reporter plasmids (2.2.13), a Dual-Luciferase[®] Reporter Assay was performed. The Dual-Luciferase[®] Reporter Assay is based on the detection of a chemi-luminescent signal, which is measured from the lysates of cells. This technique allows to evaluate whether a cloned fragment may encode for a functional MRE. If a functional MRE for miR-141-3p is present, treatment with miR-141-3p mimic should result in the binding of miR-141-3p to the fragment, and thus inhibit the expression of luciferase. The luciferase plasmids used in this thesis are the *Firefly* luciferase plasmid, which serve as the actual reporter plasmid and the *Renilla* luciferase plasmid, which were co-transfected for data normalization. These two luciferase plasmids differ in their substrate specificity and their optimal enzyme reaction catalyzation based on the adherent pH. The co-transfection of the recombinant *Firefly* plasmid and pRL-SV40 (*Renilla* plasmid) was conducted in HEK293 cells in sterile 12-well plates with an estimated confluency of 60% (~70.000 cells/well). The transfection was performed using Lipofectamin[™] 3000 (Thermo Fisher Scientific) with 300 ng *Firefly* plasmid DNA, 6.25 ng pRL-SV40 *Renilla* luciferase plasmid in either the presence or the absence of 25 pmoles of miR-141-3p mimic according to the manufacturer's instructions. After 5 hours the transfection medium was replaced by fresh culture medium and the cells were incubated for 24 hours. Afterwards, the cells were washed and lysed in 150 µL 1x Passive Lysis Buffer (Promega) for 15 min at RT. Cell lysates were transferred into reaction tubes and centrifuged at 10,000 g for 2 min at 4 °C. Next, 50 µL of the supernatant was transferred into white opaque 96-well plates. The chemiluminescence assay was performed in a GloMax[®] Multi Plus Multiplate reader (Promega) with an integrity time of 10 seconds for each individual read. Data were normalized by calculating ratios of *Firefly/Renilla* activities to correct for variations in transfection efficiencies.

2.2.15 Online databases and bioinformatic tools

miRNA sequences were acquired from *miRBASE* (Version 22.1, release October 2018, www.mirbase.org). Sequences of 3'UTRs were downloaded from *Ensembl Genome Browser* (release: Ensembl Gene database 93 at www.ensembl.org/index.html and mRNA primers for qPCR were designed using *Universal ProbeLibrary Assay Design Center* (lifescience.roche.com/en_de/brands/universal-probe-library.html#assay-design-center).

Melting temperatures for all miRNA and mRNA primers were calculated by use of the tool *Oligo Analyzer* 1.1.2 (www.genelink.com/tools/gl-oe.asp).

For target gene prediction, the online database *miRWalk* 3.0 (mirwalk.umm.uni-heidelberg.de), *TargetScan* 7.2 (www.targetscan.org), and *RNA22* (cm.jefferson.edu/rna22/) were used. *CLC Genomics Workbench* (Version 3.6.5) was utilized for virtual cloning and analysis of nucleic acids sequences received from Sanger-Sequencing. Primers for the In-Fusion Cloning Plus system were designed using Takaras web-based *In-Fusion Cloning Primer Design Tool* (www.takarabio.com/learning-centers/cloning/in-fusion-cloning-tools). QPCR data were analyzed using *qBase* software v1.3.5 and the reference gene *Rps6* was selected based on the *GeNorm* algorithm [221]. Microarray raw data were analyzed using the software *Transcriptome Analysis Console* 4.0 (Thermo Fisher Scientific). Data from luciferase assays were exported using *Instinct*[®] Software 3.1.3 (Promega).

2.2.16 Statistics

Statistical analyses were carried out with values from at least 3 independent experiments or from at least 3 different rats and are presented as means. Variations are indicated as standard error of the mean (\pm SEM). Statistical analyses for the comparisons between two groups were performed by using *GraphPad Prism* 5.03 (GraphPad Software, San Diego, USA) software, applying unpaired, two-tailed student's t-test (parametric test). For comparisons between three or more groups, the one-way ANOVA (parametric test) was applied and *p*-values smaller than 0.05 were considered significant. For comparisons between different conditions and timepoints, the two-way ANOVA (parametric test) was applied and *p*-values smaller than 0.05 were considered significant. For statistical evaluation of the GeneChip[™] miRNA 4.0 Array and Flashtag[™] Biotin HSR Labeling for miRNAs and Affymetrix GeneChip 1.0 ST, multiple t-test was applied with a false discovery rate (FDR) of 0.5% (*p*-value < 0.05).

3. Results

3.1 miRNA and mRNA expression changes in rat livers under hypoosmolarity

Previous studies by Santosa *et al.* [88] demonstrated that members of the miR-15/107 family are induced by hyperosmolarity, inducing apoptosis through the inhibition of anti-apoptotic genes in rat liver [211,225]. However, the role of miRNAs in the liver regarding the maintenance of osmotic homeostasis and osmosignaling under hypoosmolarity is largely unknown. To identify hypoosmolarity-responsive miRNAs, transcriptome-wide microarray chip analysis of hypoosmotic perfused rat liver tissue was conducted. Therefore, RNA of rat livers perfused with normoosmotic and hypoosmotic perfusion media for up to 180 min was isolated and hybridized to an Affymetrix array (GeneChip™ miRNA 4.0 Array and Flashtag™ Biotin HSR Labeling) and analyzed via *Transcriptome Analysis Console* software. Microarray analyses identified several of significantly regulated miRNAs, as depicted in Figure 3.1. When comparing miRNA levels from livers perfused with hypoosmotic medium for 180 min to normoosmotic medium, 728 miRNAs were identified, out of which 12 were downregulated, 16 were upregulated and 700 remained unchanged (Fig. 3.1 C). For instance, the following miRNAs were found to be significantly downregulated under hypoosmolarity compared to normoosmotic control after 180 min of liver perfusion:

- miR-874-3p
- miR-770-3p
- miR-541-5p.

Subsequent miRNAs were downregulated under hypoosmotic condition with a fold change of more than 2:

- miR-184
- miR-92a-5p
- miR-101b-3p.

Among 16 upregulated miRNAs under hypoosmolarity, miR-18a-5p was upregulated with a fold change of 2.1, miR-503-5p with a fold change of 2.45, and miR-350 with a fold change of 2.08. Several other miRNAs, were also upregulated under hypoosmotic condition compared to normoosmotic control, including:

- miR-155-3p
- miR-338-5p
- miR-141-3p
- miR-212-3p.

3. Results

Altogether, these data point towards an involvement of miRNAs in the cellular response to hypoosmolarity in the experimental setup of *ex vivo* liver perfusion.

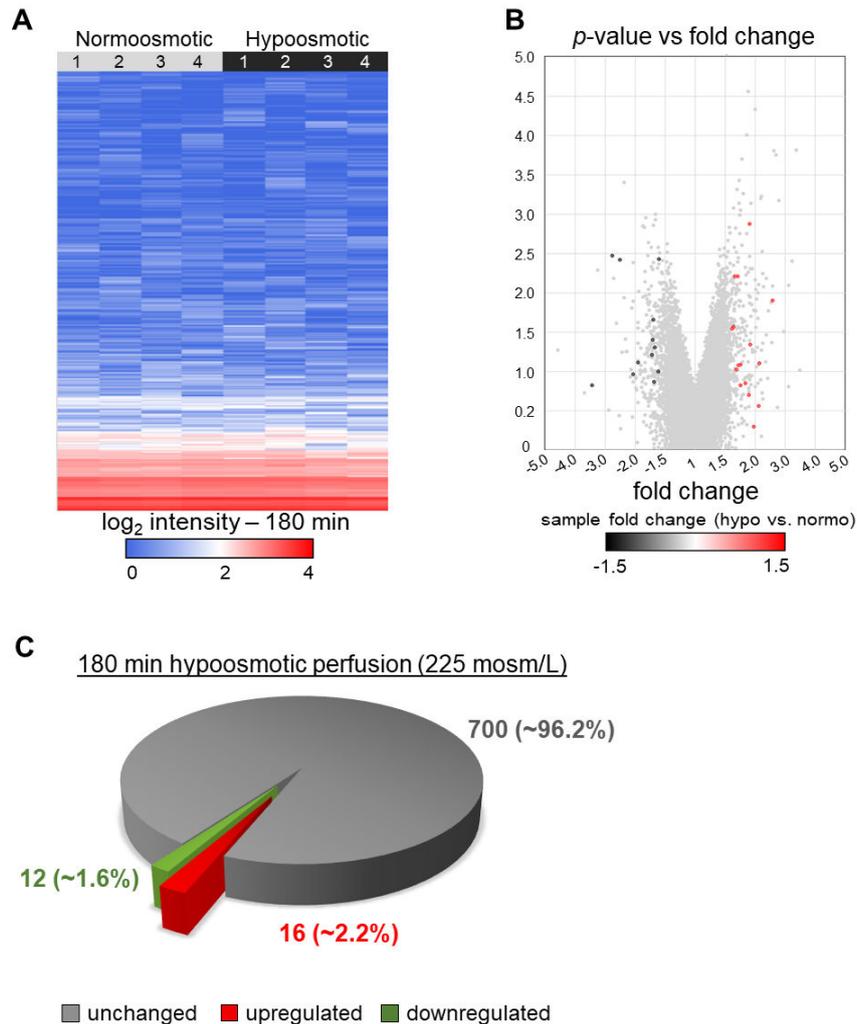

Figure 3.1 Microarray analysis of miRNAs from rat liver tissue perfused with normo- or hypoosmotic medium. Rat livers were perfused with normo- (305 mosm/L) or hypoosmotic medium (225 mosm/L) for 180 min. Livers were dissected and RNA was isolated. RNA was then hybridized to Affymetrix array (GeneChip™ miRNA 4.0 Array and Flashtag™ Biotin HSR Labeling, n=4). *Transcriptome Analysis Console* was used for data analysis by applying a cut-off of 1.5-fold change and a significance level of $p < 0.05$ (one-way ANOVA). (A) Heat map representing the hierarchical clustering of differential expressed miRNAs under normo- or hypoosmotic condition. (B) Volcano blot demonstrating differential miRNA levels after 180 min in perfused rat liver under normo- or hypoosmotic condition. A 1.5-fold change cut-off was applied with a statistical significance level of $p < 0.05$. Significantly upregulated mRNAs are labeled in red and significantly downregulated mRNAs are indicated in black, while mRNAs with non-significant changes are displayed in grey (C). Pie charts representing the number of regulated miRNAs found in rat livers after 180 min of hypoosmotic perfusion compared to normoosmotic perfusion.

To investigate the impact of hypoosmolarity on gene expression changes in rat liver perfusion, a transcriptome-wide analysis of the mRNA expression profile was conducted with normoosmotic and hypoosmotic perfused rat liver tissue. Microarray analysis revealed that after 180 min of hypoosmotic exposure, 534 mRNAs were upregulated, while 609 were

3. Results

downregulated compared to normoosmotic perfused control livers, whereas a total of 21406 mRNA remained unchanged (Fig. 3.2 C). To explore the impact of hypoosmolarity on signaling pathways via alterations in gene expression, a pathway analysis was conducted for significant upregulated mRNA using *Transcriptome Analysis Console* software. Several pathways, including the *TGF- β* signaling pathway, the $\alpha_6\beta_4$ -integrin signaling pathway, and the MAPK signaling pathway were affected by upregulated mRNA levels. Among upregulated mRNA, *cyclin B2 (Ccnb2)*, *caveolin 1 (Cav1)*, *exportin 1 (Xp1)*, and *cyclin dependent kinase inhibitor 1a (Cdkn1a)* are involved in the *TGF- β* signaling pathway, whereas *laminin subunit gamma 2 (Lamc2)* and *vimentin (Vim)* are involved in the $\alpha_6\beta_4$ -integrin signaling pathway. Altered MAPK signaling pathway was indicated by the upregulation of *fos proto-oncogene (Fos)*, *heat shock protein family A member (Hspa1a)*, and *heat shock protein family B member 1 (Hspb1)* mRNA.

These data suggest, that hypoosmotic exposure of rat livers has a pronounced effect on the levels of cellular mRNA.

3. Results

bioinformatics analyses revealed that among all of the 609 downregulated mRNAs were many miRNA target gene candidates for several miRNAs, including miR-18a-5p, miR-141-3p, miR-127-3p, miR-483-5p, and miR-338-5p. Strikingly, target prediction revealed that miR-141-3p putatively targets 249 (40.9%) out of 609 downregulated mRNAs, which were found by microarray chip analysis (Fig. 3.3 A). These data strongly point towards an involvement of miR-141-3p in the regulation of the cellular response to hypoosmolarity.

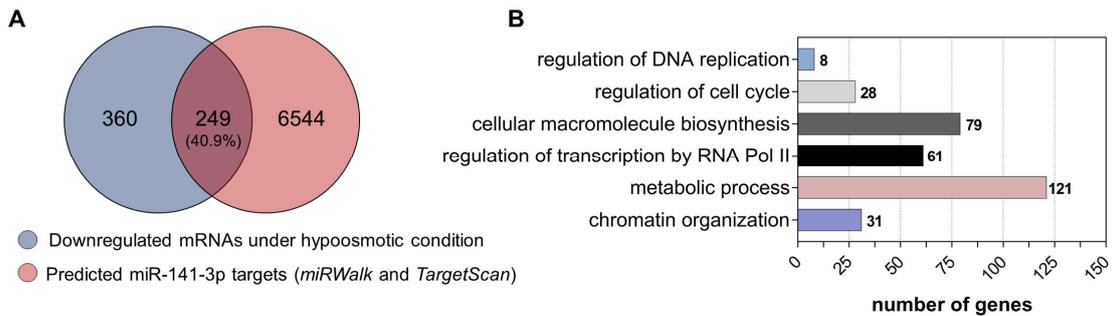

Figure 3.3 miR-141-3p target prediction analysis of significantly downregulated mRNAs under hypoosmotic conditions. (A) Venn diagram illustrating the number of downregulated mRNAs under hypoosmotic condition which identified as putative miR-141-3p target, by the target prediction algorithms *miRWalk* and *TargetScan*. (B) *Gorilla Gene Ontology enrichment* tool was utilized to analyze the predicted target gene candidates of miR-141-3p. Numbers of genes associated with given GO terms are indicated next to the bars.

To gain a better insight of the functions of miR-141-3p and the possible out-turn associated with miR-141-3p deregulation, Gene ontology enrichment analysis was conducted. All 249 identified miR-141-target gene candidates were included in this study, independent of the fold change. Gene ontology enrichment analysis revealed that the 249 miR-141-3p target gene candidates are enriched in processes such as metabolic processes, regulation of cell cycle, regulation of transcription by RNA polymerase II, cellular macromolecule biosynthesis, and chromatin organization. Thus, gene ontology enrichment analysis is indicative for an involvement of miR-141-3p in a broad spectrum of cellular mechanisms and regulations mediated via its target gene candidates. This refers to processes associated with metabolism and biosynthesis of macromolecules, e.g. proteins.

3. Results

3.3 miQPCR and qPCR validation of hypoosmotically-regulated miR-141-3p

To independently validate the observed expression changes of miR-141-3p, miQPCR was carried out on RNA isolated from rat livers perfused with normo- or hypoosmotic medium over a time course of up to 180 min. As illustrated in Figure 3.4, miR-141-3p expression was increased to 1.82-fold (± 0.26 , $p=0.027$) under hypoosmotic conditions after 180 min of rat liver perfusion. Under normoosmotic conditions miR-141-3p levels presented a stable expression during rat liver perfusion.

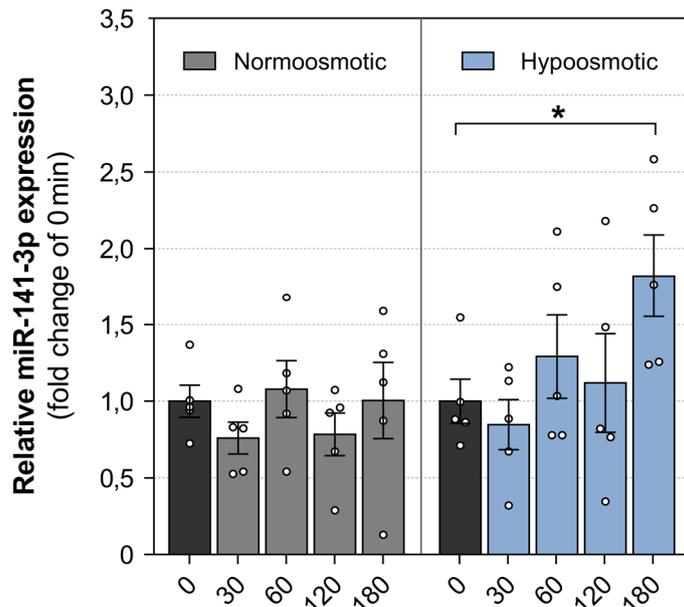

Figure 3.4 Relative quantification of miR-141-3p in perfused rat livers in response to normo- and hypoosmotic exposure. Rat livers were perfused with normo- (305 mosm/L) or hypoosmotic medium (225 mosm/L) over a time course of 180 min. After initialization of perfusion, liver lobes were dissected at the indicated time points, RNA was isolated and miRNA expression was analyzed using miQPCR ($n=5$). miRNA levels were median normalized by scaling the samples to their median value [226]. Statistical analysis was carried out by one-way ANOVA. Data are shown as average \pm standard error of the mean (SEM) with * $p<0.05$.

As a member of the miR-200 family, miR-141-3p is shown to be involved in many cellular processes, e.g. proliferation, migration, invasion, and drug resistance [227–230]. Cell swelling, induced by hypoosmotic condition in perfused rat liver is known to enhance cell proliferation [68]. For this purpose, miR-141-3p and its putative target mRNAs were picked for further investigation to investigate a possible connection with cell proliferation. For this purpose, qPCR was carried out on isolated RNA from rat livers perfused with normoosmotic or hypoosmotic medium for 180 min and mRNA levels of selected miR-141-3p target gene candidates were assessed. Specifically, putative target mRNAs associated with biological processes like proliferation, cell cycle progression, and transcriptional activity were chosen for

3. Results

qPCR analyses. These included mRNAs encoding for *Cdk8*, zinc metalloproteinase *STE24* (*Zmpste24*), cell division cycle 25A (*Cdc25a*), and nuclear factor of activated t cells 5 (*Nfat5*).

As presented in Figure 3.5, qPCR analysis of potential target gene candidates of miR-141-3p revealed differentially expressed mRNA under hypoosmotic exposure in rat liver perfusion compared to normoosmotic control.

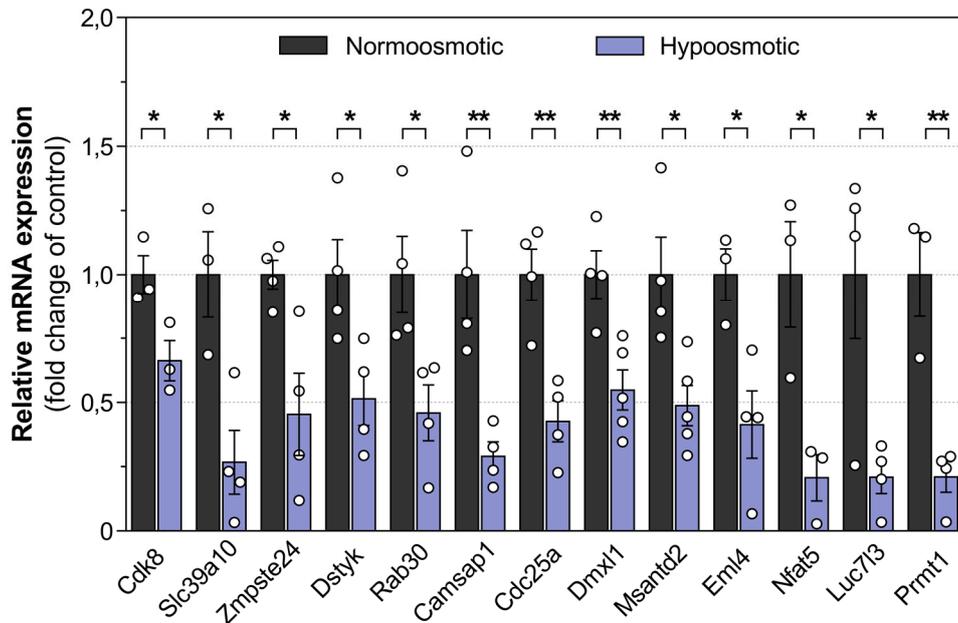

Figure 3.5 Quantitative analysis of putative target mRNA of miR-141-3p in perfused rat livers in response to normo- and hypoosmotic exposure. Rat livers were perfused with normo- (305 mosm/L) or hypoosmotic medium (225 mosm/L) for 180 min. Livers were dissected, RNA was isolated, and miRNA expression was analyzed using qPCR (n=3-5). qPCR values were normalized to *Rps6* mRNA levels. Statistical analysis was carried out by student's t-test. Data are shown as average ± SEM with * $p < 0.05$ and ** $p < 0.01$.

Under hypoosmotic exposure selected mRNA levels of putative miR-141-3p target genes were significantly downregulated compared to normoosmotic control as displayed in Table 3.3.1:

Table 3.3.1 mRNA levels of putative target mRNA of miR-141-3p

Name	Identifier	downregulated to	p-value
Cyclin dependent kinase 8	<i>Cdk8</i>	0.66-fold ± 0.07	0.035
Solute carrier family 39 member 10	<i>Slc39a10</i>	0.26-fold ± 0.12	0.015
Zinc metalloproteinase STE24	<i>Zmpste24</i>	0.45-fold ± 0.15	0.018
Dual serine/threonine and tyrosine protein kinase	<i>Dstyk</i>	0.51-fold ± 0.10	0.029
Member ras oncogene family	<i>Rab30</i>	0.45-fold ± 0.05	0.026
Calmodulin regulated spectrin associated protein 1	<i>Camsap1</i>	0.29-fold ± 0.07	0.007
Cell division cycle 25A	<i>Cdc25a</i>	0.42-fold ± 0.07	0.004
Dmx like 1	<i>Dmx1</i>	0.54-fold ± 0.07	0.007
Myb/SANT DNA binding domain containing 2	<i>Msantd2</i>	0.48-fold ± 0.07	0.013
EMAP like 4	<i>Eml4</i>	0.41-fold ± 0.13	0.020

3. Results

Table 3.3.1 mRNA levels of putative target mRNA of miR-141-3p (continued)

<i>Nuclear factor of activated t cells 5</i>	<i>Nfat5</i>	0.20-fold \pm 0.09	0.024
<i>LUC7 like 3 pre-mRNA splicing factor</i>	<i>Luc7l3</i>	0.20-fold \pm 0.06	0.024
<i>Protein arginine methyltransferase 1</i>	<i>Prmt1</i>	0.21-fold \pm 0.05	0.003

As illustrated in Figure 3.5 and shown in Table 3.3.1, all selected mRNA were significantly downregulated after 180 min of hypoosmotic rat liver perfusion.

Table 3.3.2 shows several genes which are not affected on their mRNA level by hypoosmotic exposure in rat liver perfusion, to emphasize the distinct effect of hypoosmolarity on specific mRNA.

Table 3.3.2 mRNA not affected by hypoosmotic exposure

Name	Identifier	Fold-change	p-value

3.4 Analysis of miR-141-3p in isolated primary rat hepatocytes.

To investigate whether changes in miR-141-3p levels and its putative target gene mRNA levels can be mimicked *in vitro*, exposure of primary rat hepatocytes to hypoosmotic medium was performed, since hepatic parenchymal cells constitute about 70% of all liver cells and represent the basic structural component of the liver [231]. Figure 3.6 A and B display microscopical images of isolated primary rat hepatocytes exposed to normo- and hypoosmotic medium. Hypoosmotic exposure resulted in an increased cell surface and swelling of the cell nucleus. To assess the extent of cell swelling, cell nucleus diameters were measured and compared between the two conditions (Fig. 3.6 C). Isolated primary rat hepatocytes, which were exposed to normoosmotic medium for 5 min, had an average cell nucleus diameter of 9.7 μ m (\pm 1.2 μ m). Hypoosmotic exposure led to an average cell nucleus diameter of 13.1 μ m (\pm 2.0 μ m) after 5 min, resulting in a diameter increase by about 35% ($p=0.001$, Fig. 3.6 D). After 3 h of hypoosmotic exposure, the average cell nucleus diameter decreased back to 10.4 μ m (\pm 1.3 μ m). This resulted in an increased diameter by about 7% compared to normoosmotic control, due to counteractive volume regulatory mechanisms (RVD).

3. Results

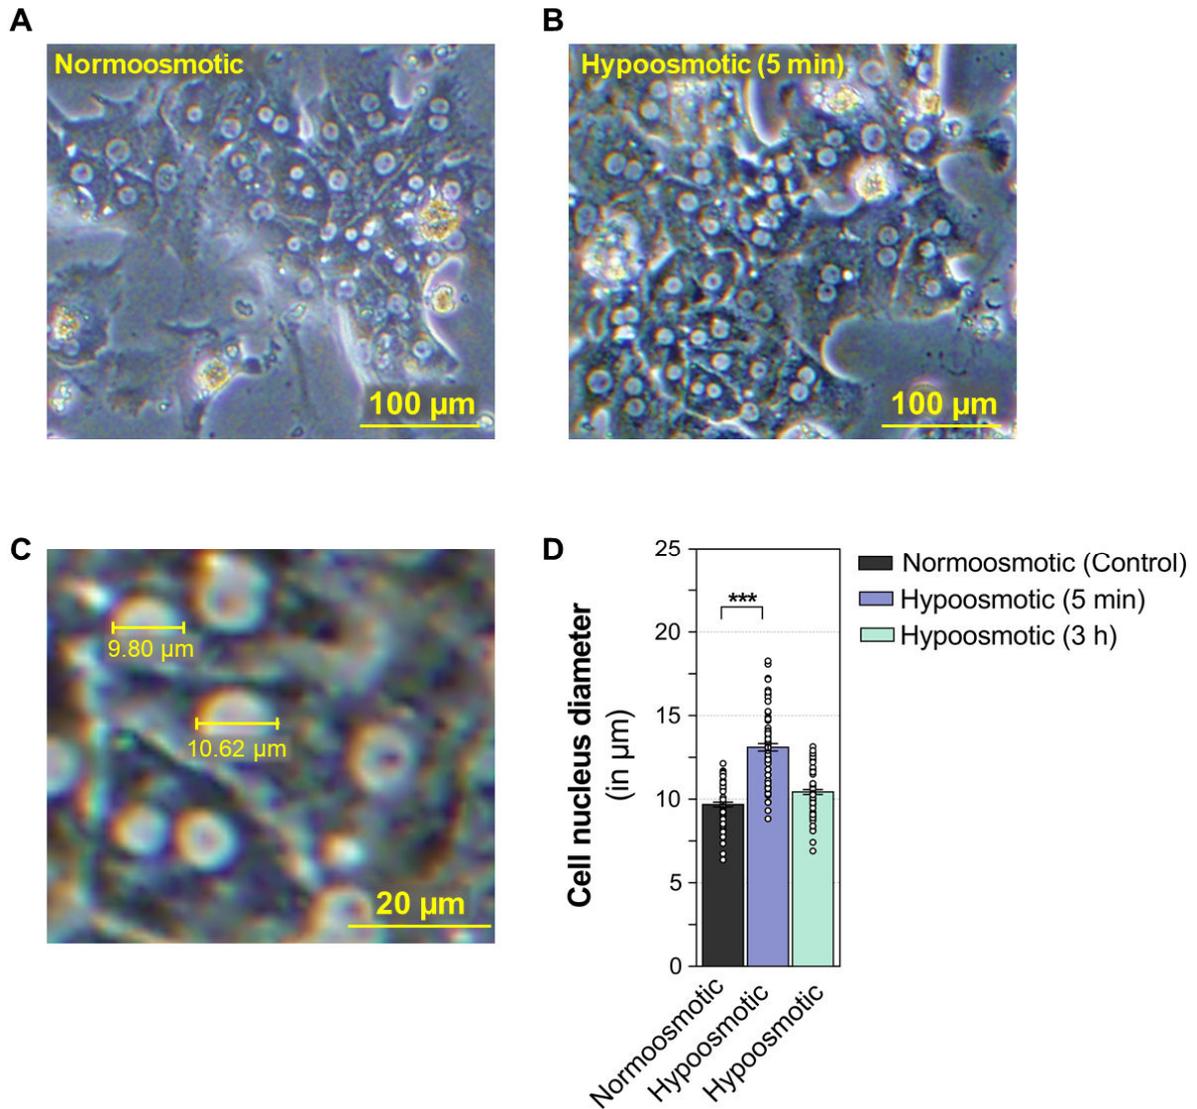

Figure 3.6 Effect of normo- and hypoosmotic exposure on the cell nucleus of rat primary hepatocytes. To determine the extent of cell swelling on rat primary hepatocytes cell nucleus diameters were measured in rat primary hepatocytes, which were exposed to (A) normo- (305 mosm/L) or (B) hypoosmotic medium (225 mosm/L) over a duration of 5 min. (C) Example of measurement of the cell nucleus diameter. (D) Mean cell nucleus diameters were compared between normo- and hypoosmotic condition using *cellSens Dimension* software. For statistical analysis, the diameters of a total of 80 nuclei were assessed. Statistical analysis was carried out by unpaired student's t-test. Data are shown as average \pm SEM with *** $p < 0.001$.

With the aim to investigate whether hypoosmotic-induced overexpression of miR-141-3p can be mimicked in isolated primary rat hepatocytes, miQPCR was conducted for the relative quantification of miR-141-3p levels. As depicted in Figure 3.7, miR-141-3p levels remained stable within 3 h of normo- and hypoosmotic exposure. However, after 24 h of hypoosmotic exposure miR-141-3p expression levels increased to 2.17-fold (± 0.27 , $p = 0.006$), while it remained stable under normoosmotic exposure.

3. Results

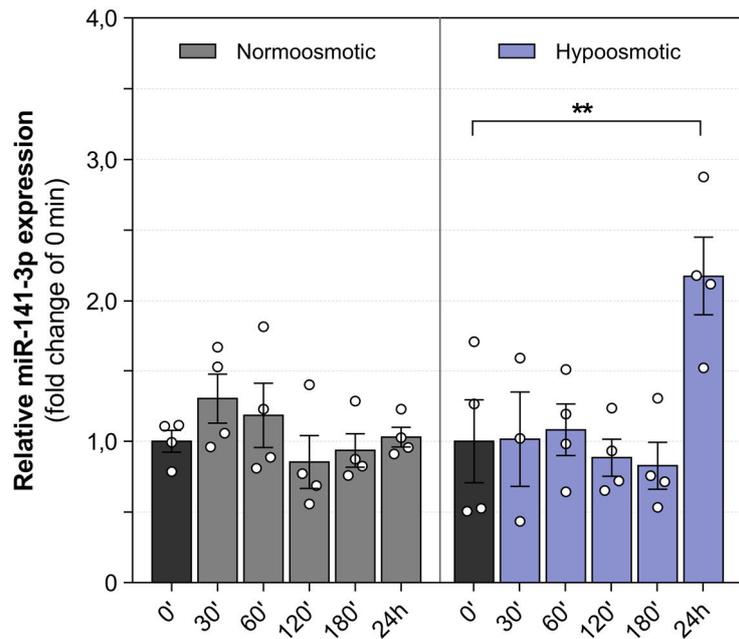

Figure 3.7 Quantitative qPCR analysis of miRNA miR-141-3p in primary rat hepatocytes in response to normo- and hypoosmotic exposure. Isolated primary rat hepatocytes were treated with normo- (305 mosm/L) or hypoosmotic medium (225 mosm/L) for up to 24 h. Following RNA isolation, miRNA expression was analyzed using miQPCR (n=3-4). miRNA levels were median normalized by scaling the samples to their median value [226]. Statistical analysis was carried out by one-way ANOVA. Data are shown as average \pm SEM with ** $p < 0.01$.

Next, qPCR was conducted to assess whether the selected putative target mRNAs of miR-141-3p shown in Figure 3.5 are inversely related to miR-141-3p levels in isolated primary rat hepatocytes as well (Fig. 3.8). After 24 h of hypoosmotic exposure to primary rat hepatocytes *Slc39a10* were significantly downregulated to 0.40-fold (± 0.03 , $p=0.006$), *Dstyk* to 0.68-fold (± 0.06 , $p=0.016$), *Rab30* to 0.75-fold (± 0.06 , $p=0.042$), *Cdc25a* to 0.58-fold (± 0.04 , $p=0.022$), *Dmxl1* to 0.64-fold (± 0.03 , $p=0.041$), and *Nfat5* to 0.38-fold (± 0.02 , $p=0.002$) as compared to normoosmotic control.

3. Results

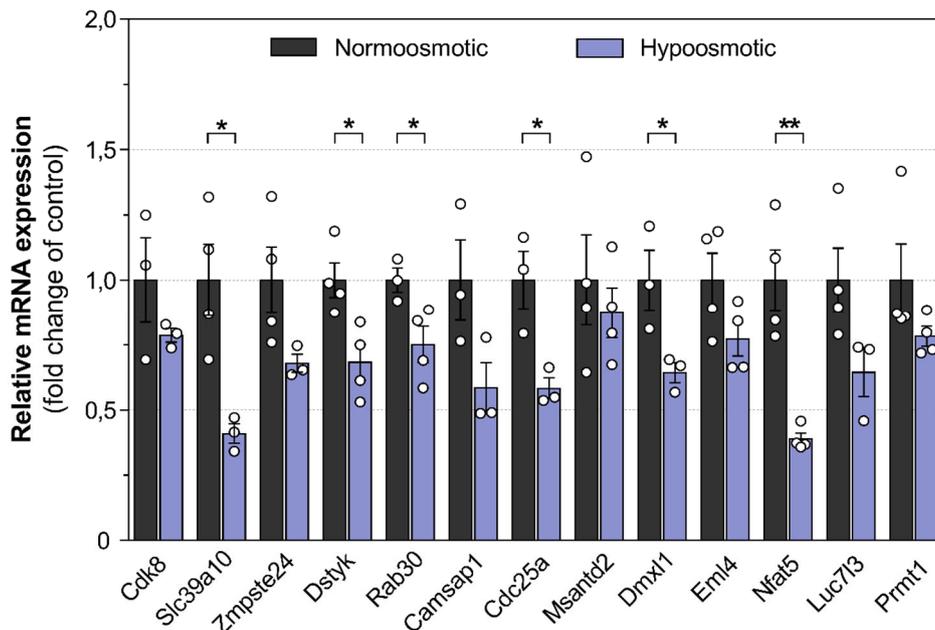

Figure 3.8 Quantitative qPCR analysis of putative target mRNA of miR-141-3p in primary rat hepatocytes in response to normo- and hypoosmotic exposure. Isolated primary rat hepatocytes were treated with normo- (305 mosm/L) or hypoosmotic medium (225 mosm/L) over a time course of up to 24 h. Following RNA isolation, mRNA expression was analyzed using qPCR (n=3-4). qPCR runs were normalized to *Rps6* mRNA levels. Statistical analysis was carried out by student's t-test. Data are shown as average \pm SEM with * $p < 0.05$.

Cdk8, *Zmpste24*, *Camsap1*, *Msantd2*, *Eml4*, *Luc7l3*, and *Pmrt1* mRNA levels showed a tendency towards downregulation, without reaching significance. Overall, all selected putative target mRNAs of miR-141-3p showed decreased mRNA levels after 24 h of hypoosmotic exposure in comparison with normoosmotic controls. Collectively, these data indicate that the effect of hypoosmotic exposure in rat liver perfusions can be mimicked in isolated primary rat hepatocytes, resulting in enriched miR-141-3p levels and decreased mRNA levels of selected putative target genes.

3.5 Overexpression of miR-141-3p in primary rat hepatocytes

To evaluate whether overexpression of miR-141-3p is sufficient to induce downregulation of putative target mRNAs, miR-141-3p mimic transfections were conducted in isolated primary rat hepatocytes. Figure 3.9 displays the successful overexpression of miR-141-3p in isolated primary rat hepatocytes. Cellular levels of miR-141-3p were enriched by 2,033-fold ($p=0.004$) at 24 h and by 6,800-fold ($p=0.001$) at 48 h post transfection, indicating a successful overexpression of miR-141-3p in the target cells.

3. Results

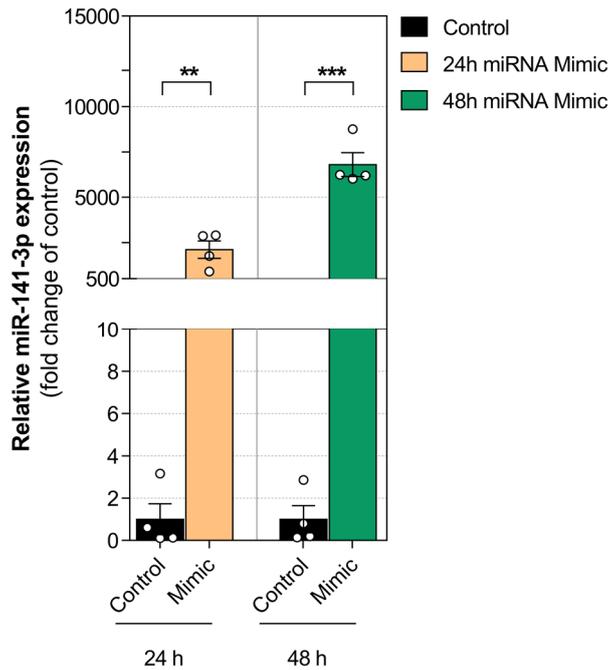

Figure 3.9 Quantitative qPCR analysis of cellular miR-141-3p levels in miR-141-3p mimic transfected primary rat hepatocytes. Primary rat hepatocytes were transfected with miR-141-3p mimic for 24 or 48 h. Control groups were mock-transfected in absence of miR-141-3p mimic. Cells were washed, lysed, RNA was isolated, and miRNAs were quantified using miQPCR. miRNA levels were median normalized by scaling the samples to their median value [226] and statistical analysis was carried out by student's t-test (n=3). Data are shown as average \pm SEM with ** $p < 0.01$ and *** $p < 0.001$.

In the next step, levels of selected target mRNA candidates were investigated via qPCR. Figure 3.10 shows the relative amount of selected mRNA levels after 24 h (A) and 48 h (B) post mimic transfection. A tendency for downregulation after 24 h post transfection was observed for the putative target mRNA *Nfat5* ($p=0.067$), however without reaching significance (Fig. 3.10 A).

3. Results

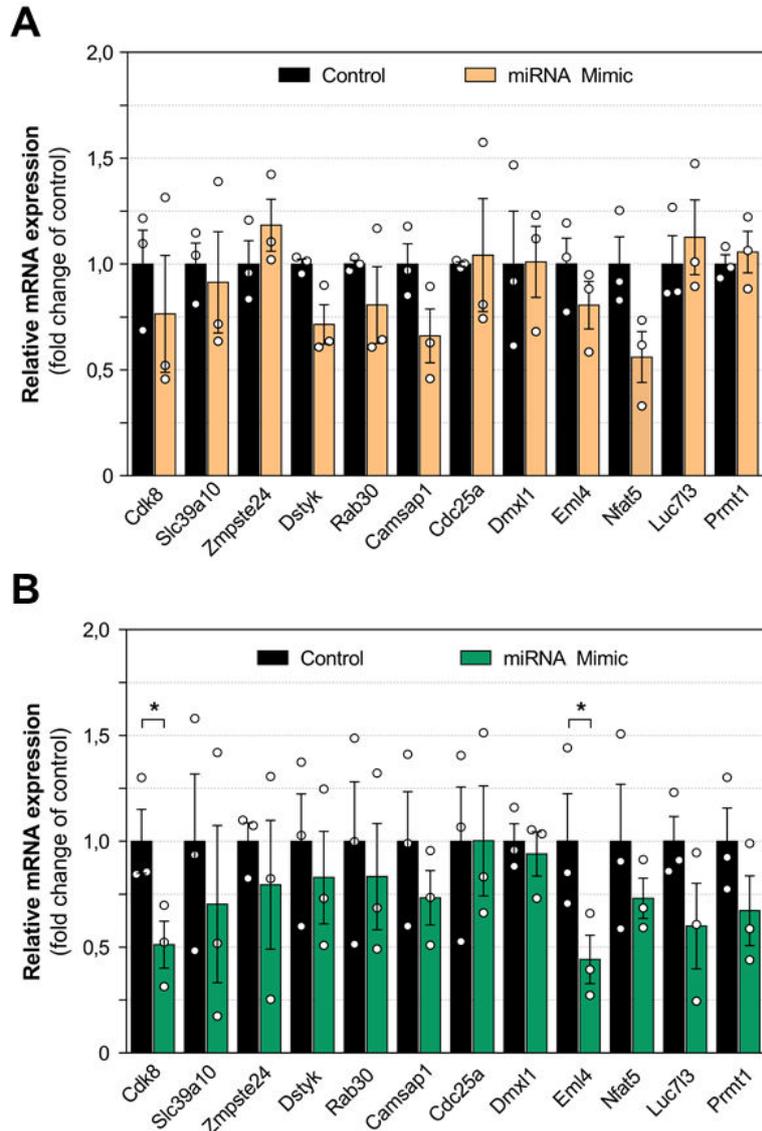

Figure 3.10 Relative mRNA levels of putative miR-141-3p target mRNAs in primary rat hepatocytes transfected with miR-141-3p mimic. Primary rat hepatocytes were transfected with miR-141-3p mimic for 24 h (A) or 48 h (B). Control groups were mock-transfected in absence of miR-141-3p mimic. Cells were washed, lysed, RNA was isolated, and mRNAs were quantified using qPCR. qPCR runs were normalized to *Rps6* mRNA levels. Data represent average \pm SEM of 3 independent experiments. Statistical analysis was carried out by student's t-test with * $p < 0.05$.

After 48 h, however, a significant downregulation of *Cdk8* mRNA by 0.49-fold (± 0.11 , $p=0.047$) and *Eml4* mRNA by 0.56-fold (± 0.11 , $p=0.026$) was observed in cells transfected with miR-141-3p mimic in comparison to control cells. *Nfat5* mRNA levels ($p=0.078$) showed a tendency for downregulation, although the effects did not match statistical significance.

3.6 Validation of *Cdk8* as a target gene of miR-141-3p

As an important regulator of cell cycle progression, *Cdk8* was selected for further target validation. For this purpose, binding site analysis was conducted using the miRNA target discovery algorithm *RNA22*. *RNA22* identifies binding sites by screening the complementarity of the selected miRNA and the transcript and the folding energy which is released upon formation of the miRNA-mRNA heteroduplex [232]. This bioinformatic approach revealed that the 3'UTR of *Cdk8* mRNA harbors two potential binding sites (miRNA response elements - MREs) for miR-141-3p, as depicted in Figure 3.11.

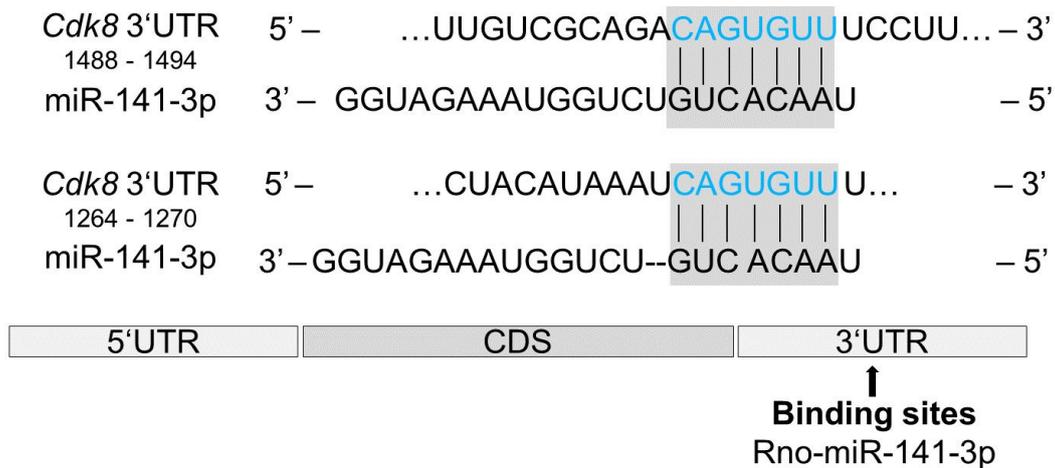

Figure 3.11 Putative miR-141-3p binding sites on the 3'UTR of rat *Cdk8* mRNA. *RNA22* predicted two binding sites for miR-141-3p in the 3'UTR of rat *Cdk8* mRNA. Black lines indicate predicted base pairing between miR-141-3p and target sequence. The seed sequence of miR-141-3p is indicated in grey boxes and corresponding nucleic acids are displayed in blue font.

The miRNA target discovery algorithm *RNA22* suggests that *Cdk8* mRNA may be directly targeted by miR-141-3p on two different binding sites encoded in the 3'UTR. Previous analyses presented in this study displayed that upregulation of miR-141-3p decreased the mRNA levels of *Cdk8* (Fig. 3.5, Fig. 3.8, and Fig. 3.10 B). To further assess and verify the direct interaction between miR-141-3p and *Cdk8* mRNA, a luciferase-based reporter assay was performed (Section 2.2.14). For this purpose, the full-length sequence of *Cdk8* 3'UTR was cloned into pMir(+) and pMir(-) reporter plasmids, whereas pMir(-) serves as a negative control plasmid. The recombinant luciferase plasmids were transfected into HEK293 in presence or absence of miR-141-3p mimic, respectively.

3. Results

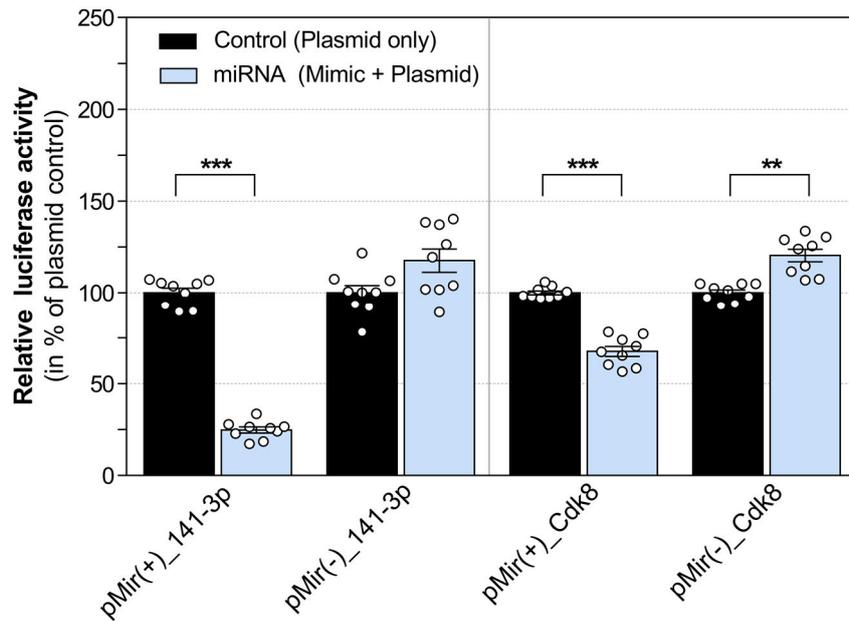

Figure 3.12 Validation of rat *Cdk8* 3'UTR as a direct target site for miR-141-3p. HEK293 cells were transfected with recombinant plasmids either in absence (black) or in presence of miR-141-3p mimic (light blue). Luciferase activity was measured from cell lysates 24 h post transfection. Data are represented as percentage \pm SEM of 3 independent experiments. As control, luciferase activity in absence of miR-141-3p was set to 100%. Asterisks indicate significant differences between groups, student's t-test with significance level ** $p < 0.01$, *** $p < 0.001$.

Figure 3.12 displays the luciferase activity of pMir(+)_141-3p transfected cells which were co-transfected with miR-141-3p mimic or mock transfected. In presence of miR-141-3p mimic luciferase activity was significantly decreased to 24.7% ($\pm 1.6\%$, $p=0.001$) after 24 h post transfection. These data indicated that the product of pMir(+)_141-3p vector harbors a perfect miR-141-3p MRE. Luciferase activity from cells transfected with pMir(-)_141-3p, which harbored the perfect miR-141-3p binding site in its inverse orientation (negative control), was not inhibited by the co-transfection with miR-141-3p mimic (Fig. 3.12). A significant change in luciferase activity was observed in cells transfected with pMir(+)_Cdk8. In presence of miR-141-3p mimic luciferase activity was decreased to 67.5% ($\pm 2.6\%$, $p=0.001$) in comparison to cells transfected with plasmid in absence of miR-141-3p mimic. In cells transfected with pMir(-)_Cdk8, luciferase activity was increased by 20.3% ($\pm 3.4\%$, $p=0.005$) in presence of miR-141-3p mimic. To summarize, the observed changes in luciferase activity can be ascribed to the binding of miR-141-3p to the luciferase transcript, resulting in a miRNA-mediated repression, thus leading to decreased luciferase protein levels. Therefore, these data provided the evidence for a direct interaction between miR-141-3p and the cloned 3'UTR of *Cdk8* mRNA as illustrated in Figure 3.11.

3.7 Expression of miR-141-3p and *Cdk8* mRNA after partial hepatectomy (PHx).

Studies from Gao *et al.* showed that miR-141-3p plays a role in cell proliferation in different types of tissues [233], but whether miR-141-3p and *Cdk8* may also be involved in proliferative processes in the liver is not yet confirmed. To investigate an involvement of miR-141-3p and *Cdk8* in proliferative processes like liver regeneration, quantitative PCR analysis of miR-141-3p and *Cdk8* mRNA expression levels was conducted with tissue from livers of 10 weeks old rats, in whom PHx had been performed and who recovered from this drastic surgical measure for a period of up to 14 days (Fig. 3.13).

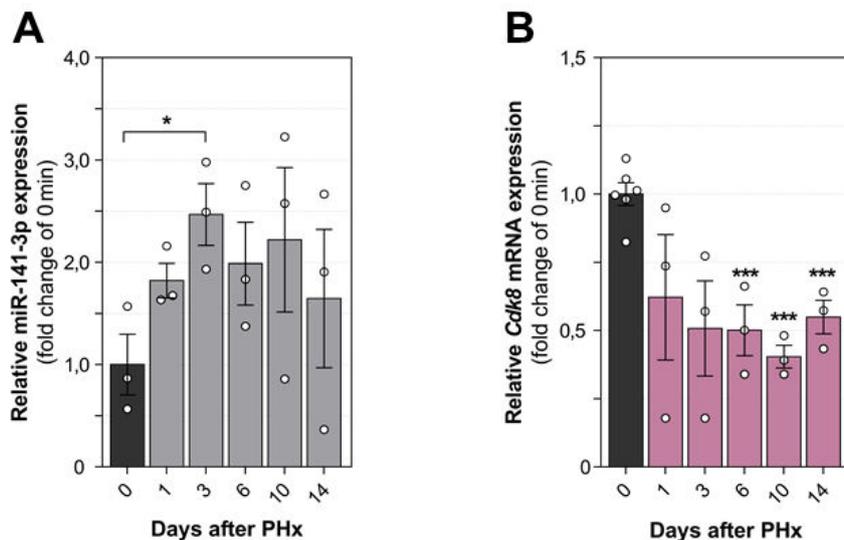

Figure 3.13 Effects of partial hepatectomy on levels of miR-141-3p and *Cdk8* mRNA in rat livers. Rats at the age of 10 weeks were subjected to partial hepatectomy (PHx) as described by Higgins *et al.* [113]. Rats were sacrificed after 0-14 days as indicated. Hepatic RNA was isolated and levels of miR-141-3p and *Cdk8* were analyzed by qPCR. **(A)** Levels of miR-141-3p in the livers of partial hepatectomized rat. miRNA levels were median normalized by scaling the samples to their median value [226]. **(B)** Relative *Cdk8* levels in the liver of rat subjected to PHx. qPCR runs were normalized to *Rps6* mRNA levels. Statistical analysis was carried out by one-way ANOVA (n=3-6, data are shown as average \pm SEM with * $p < 0.05$ and *** $p < 0.001$).

As illustrated in Figure 3.13 A, the levels of miR-141-3p transiently increased by 1.82-fold (± 0.16 , $p=0.07$) after 1 day and 2.46-fold (± 0.3 , $p=0.02$) after 3 days after PHx, when parenchymal and non-parenchymal cells proliferate to reconstitute the liver mass. At later time points during liver regeneration, no significant upregulation of miR-141-3p was observed. In contrast, *Cdk8* mRNA levels decreased, showing the lowest values 10 days after PHx (0.4-fold ± 0.04 , $p=0.001$, Fig. 3.13 B). These findings suggest that miR-141-3p and its target gene *Cdk8* might be involved in liver regeneration and associated with cell proliferation.

3.7 Mechanical stimulation of isolated primary rat hepatocytes

The stretching of liver cells occurs during hypoosmotic induced cell swelling, cell division, and liver regeneration [114,234]. Mechanical stimulation of cells is sensed by several mechanisms that also include integrins resulting in Src-, Erk-, and p38^{MAPK} signaling [235]. This process is referred to as ‘mechanotransduction’ [116]. To gain further insights into potential factors which enable the upregulation of miR-141-3p, rat primary hepatocytes exposed to a mechanical stimulation were investigated. For this reason, isolated rat primary hepatocytes were seeded on flexible thin silica membrane chambers (STB-100, STREX), which allows the appliance of a tractive force.

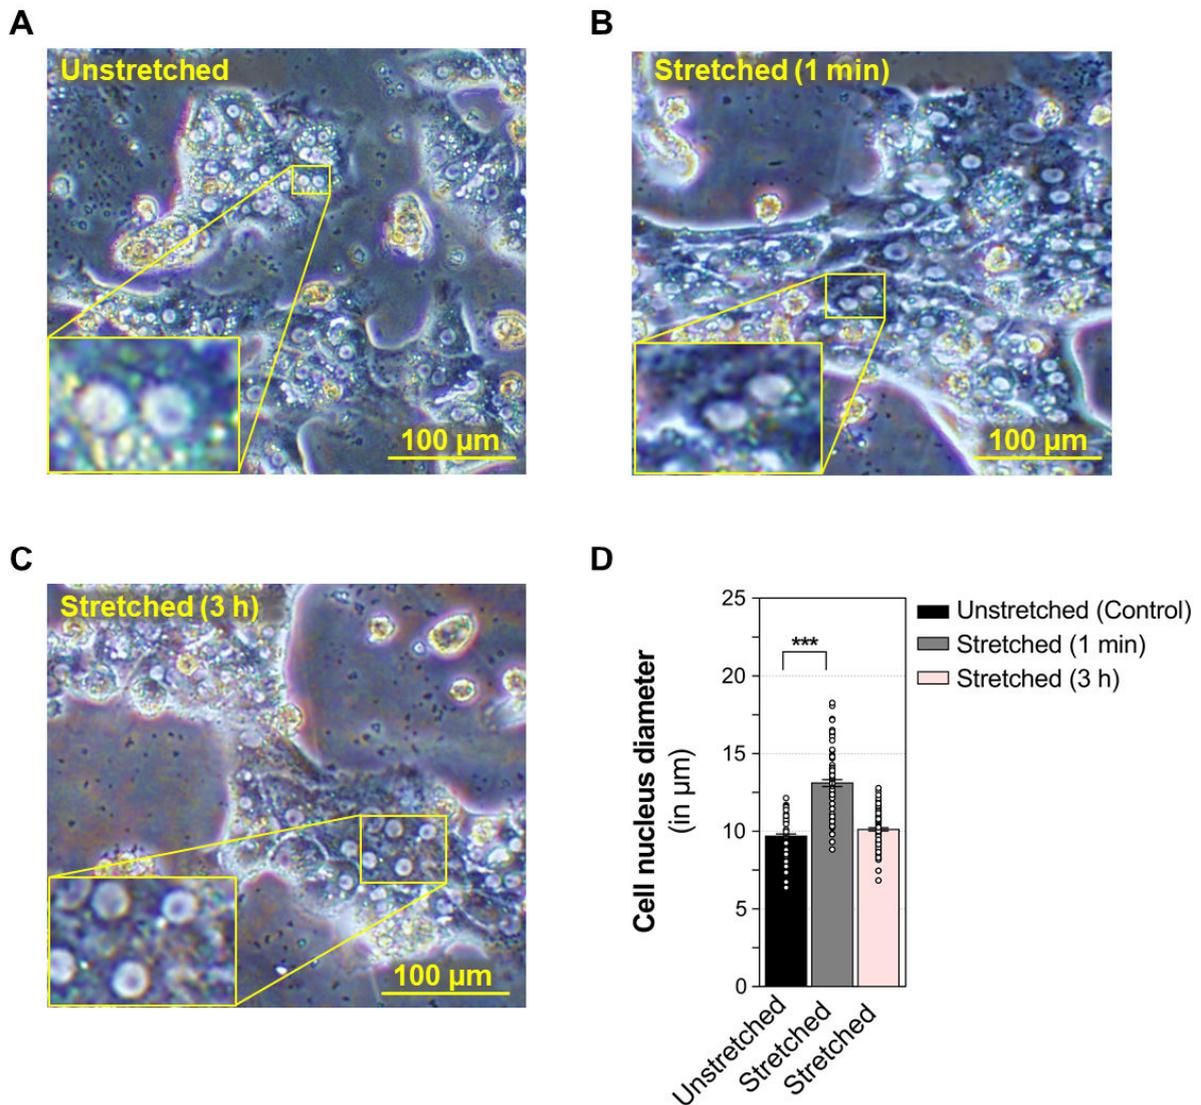

Figure 3.14 Effect of mechanical stimulation on cell nucleus diameters of primary rat hepatocytes. Primary rat hepatocytes were seeded on silicone stretch chambers and remained unstretched (A) or were stretched (B and C). Representative images of groups of nuclei are displayed in 2-3-fold magnification in the left lower corner. (D) Mean cell nucleus diameters were compared between stretched and unstretched primary rat hepatocytes using *cellSens Dimension* software. For statistical analysis, the diameters of a total of 80 nuclei were assessed. Statistical analysis was carried out by unpaired student's t-test. Data are shown as average \pm SEM with *** $p < 0.001$.

3. Results

Figure 3.14 depicts microscopical images on isolated primary rat hepatocytes seeded on silicone stretch chambers which remained unstretched (Fig. 3.14 A) or which were subjected to stretching (Fig. 3.14 B and C). Cell nucleus diameters were measured and the average unstretched cell nucleus showed a diameter of $9.7 \mu\text{m}$ ($\pm 1.2 \mu\text{m}$), whereas stretched cells exhibited an increased diameter of $12.8 \mu\text{m}$ ($\pm 2.1 \mu\text{m}$). The mechanical stimulation resulted in an increased cell nucleus diameter by 31.6% ($p=0.001$). After 3 h of stretching the cells reshaped back to their initial size and their cell nucleus turned back to an average of $10.0 \mu\text{m}$ ($\pm 1.3 \mu\text{m}$). All measurements were taken immediately after the stretching of the cells. The effect of mechanical stretching on the relative levels of miR-141-3p and *Cdk8* mRNA in hepatocytes was investigated by miQPCR and qPCR, respectively.

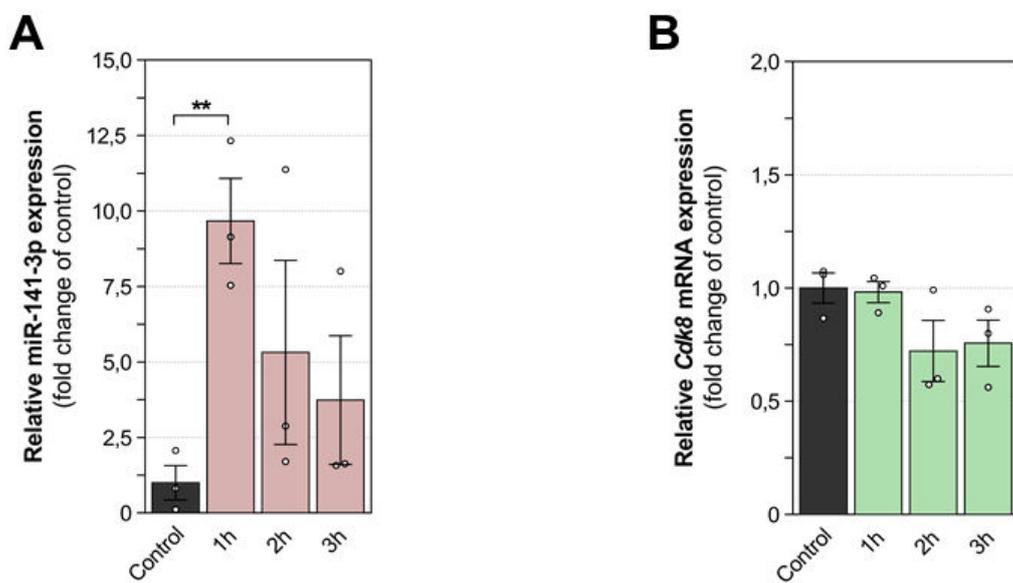

Figure 3.15 Effect of mechanical stimulation on miR-141-3p and *Cdk8* mRNA expression in primary hepatocytes. Primary rat hepatocytes were seeded on silicone stretch chambers and either stretched by roughly 30% or remained unstretched as a control. **A)** Levels of miR-141-3p in primary rat hepatocytes during cell stretching at indicated time points. **B)** *Cdk8* mRNA amount in primary rat hepatocytes during stretching. The cells were washed, lysed, and RNA was isolated. Levels of miR-141-3p were analyzed by miQPCR, *Cdk8* mRNA amounts were analyzed by qPCR, and values were normalized to *Rps6* mRNA levels. miQPCR data were median normalized by scaling the samples to their median value [226]. Statistical analysis was carried out by one-way ANOVA ($n=3$, data are shown as average \pm SEM with ** $p<0.01$).

Expression of miR-141-3p was increased to 9.67-fold (± 1.4 , $p=0.004$) 1 h after stretching of hepatocytes. miR-141-3p expression was increased to 5.31-fold (± 3.0) after 2 h, and to 3.72-fold (± 2.1) after 3 h, but without reaching significance as illustrated in Figure 3.15 A. In contrast, *Cdk8* mRNA levels remained stable for 1 h after cell stretching and showed a tendency towards downregulation after 2 h (0.72-fold ± 0.1) and 3 h (0.75-fold ± 0.1), without reaching significance (Fig. 3.15 B).

3. Results

Altogether, the cell stretching accompanied by an enrichment in miR-141-3p levels did not influence *Cdk8* mRNA levels on the same level as seen after hypoosmotic exposure (Fig. 3.5 and Fig. 3.8), mimic transfection (Fig. 3.10 B), and PHx (Fig. 3.13 B). It is therefore conceivable that *Cdk8* mRNA expression levels may also be influenced by other factors such as growth factors released by neighboring cells of hepatocytes or ion channels which may not be responsive to the application of a mechanical stimulus.

3.8 Rat liver perfusions with Src-, Erk-, and p38^{MAPK} inhibitors

Hypoosmotic exposure results in an activation of $\alpha_5\beta_1$ - integrins signaling and a subsequent activation of Src-, Erk-1/Erk-2, and p38^{MAPK} kinases [235]. To investigate the potential role of these osmosensing and osmosignaling pathways in the observed upregulation of miR-141-3p, rat liver perfusion were conducted in presence of Src (PP-2), Erk-1/2 (PD098059), and p38^{MAPK} (PD169316) inhibitors.

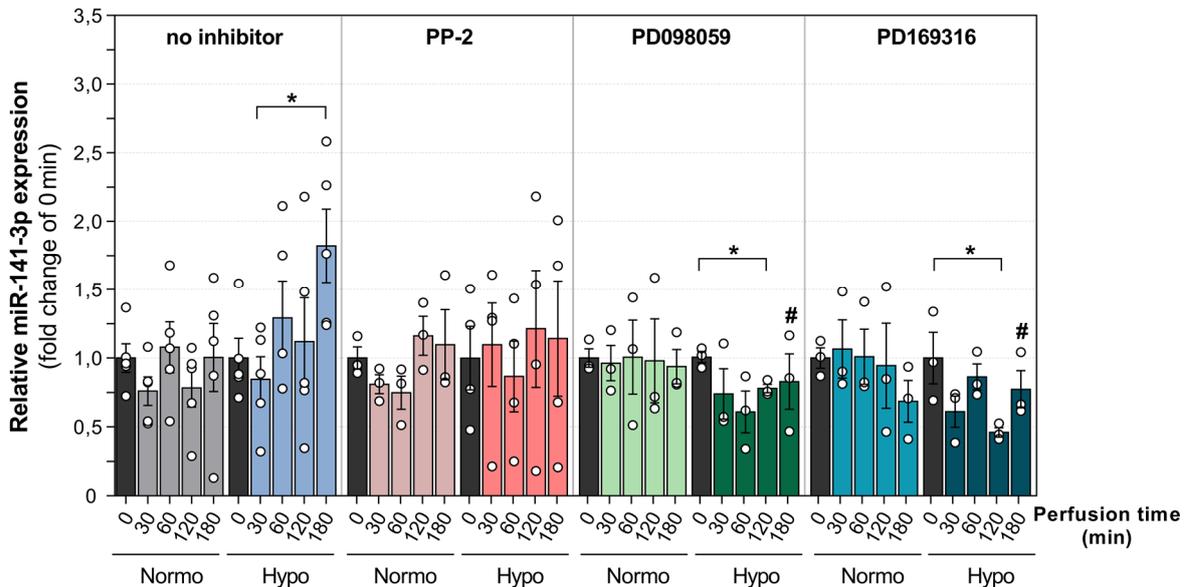

Figure 3.16 Analysis of miR-141-3p levels by hypoosmolarity in presence of Src-, Erk-, and p38^{MAPK}-inhibitors. Rat livers were perfused with normo- (305 mosm/L) or hypoosmotic (225 mosm/L) medium for 0-180 min. Inhibitors of Src (PP-2, 250 nM), Erk (PD098059, 500 nM) and p38 (PD169316, 250 nM) were added to the perfusate as indicated. After initialization of perfusion, liver lobes were dissected at the indicated time points, RNA was isolated, and miR-141-3p expression was quantified by miQPCR. Data represent the relative levels of miR-141-3p as percentage to the preperfusion state (0 min). miRNA levels were median normalized by scaling the samples to their median value [226]. Statistical analysis was carried out by two-way ANOVA. (n=3-4, data are shown as average \pm SEM with * $p < 0.05$ for significance against 0 min of the respective condition, # indicates $p < 0.05$ against 180 min of hypoosmotic perfusion with no inhibitors).

Addition of Src inhibitor PP-2 to the perfusate had no significant effect on miR-141-3p expression levels under normo- or hypoosmotic condition but prevented a miR-141-3p upregulation as observed in absence of PP-2 inhibitor (Fig. 3.16 left). Supplementation of the

3. Results

Erk inhibitor PD098059 to the hypoosmotic perfusion buffer resulted in a transient downregulation of miR-141-3p levels after 60 min with a significant reduction after 120 min to 0.77-fold (± 0.03 , $p=0.011$) in comparison to the preperfusion state (0 min). Addition of Erk inhibitor to hypoosmotic perfusion resulted in a significant lower miR-141-3p level after 180 min of perfusion compared to 180 min of hypoosmotic perfusion with no supplemented inhibitors (# indicates $p=0.042$). In contrast, normoosmotic controls containing PD098059 in the perfusion buffer remained stable (Fig. 3.16 middle).

Addition of p38^{MAPK} inhibitor PD169316 resulted in a transient downregulation under hypoosmolarity compared to the normoosmotic condition. Expression levels of miR-141-3p decreased after 30 min to 0.61-fold (± 0.11 , $p=0.149$) and after 120 min significant to 0.46-fold (± 0.03 , $p=0.046$, Fig. 3.16 right). Addition of p38^{MAPK} inhibitor to hypoosmotic perfusion resulted in significant lower miR-141-3p levels compared to 180 min of hypoosmotic perfusion without supplemented inhibitors (# indicates $p=0.030$). Overall, inhibitor perfusion studies revealed that hypoosmotic-induced miR-141-3p upregulation was abolished under hypoosmotic exposure through addition of Src-, Erk-, and p38^{MAPK} kinases inhibitors. Collectively, these data indicate that miR-141-3p expression levels are dependent on Src-, Erk-, and p38^{MAPK} signaling.

3. Results

3.9 Rat liver perfusion with colchicine

Hypoosmotic induced osmosignaling and downstream activation of p38^{MAPK} kinase is known to inhibit proteolysis [18]. However, this inhibitory effect resulting from hypoosmotic exposure can be abolished by the addition of colchicine to the perfusate [236]. Colchicine is a well-known microtubule inhibitor, which prevents microtubule assembly and therefore inhibits the microtubule- and p38^{MAPK}-dependent autophagic proteolysis [237]. To further investigate the involvement of p38^{MAPK} in hypoosmolarity-induced effects on miR-141-3p levels in liver cells (e.g. involvement in metabolic processes), rat liver perfusions in presence of colchicine were conducted.

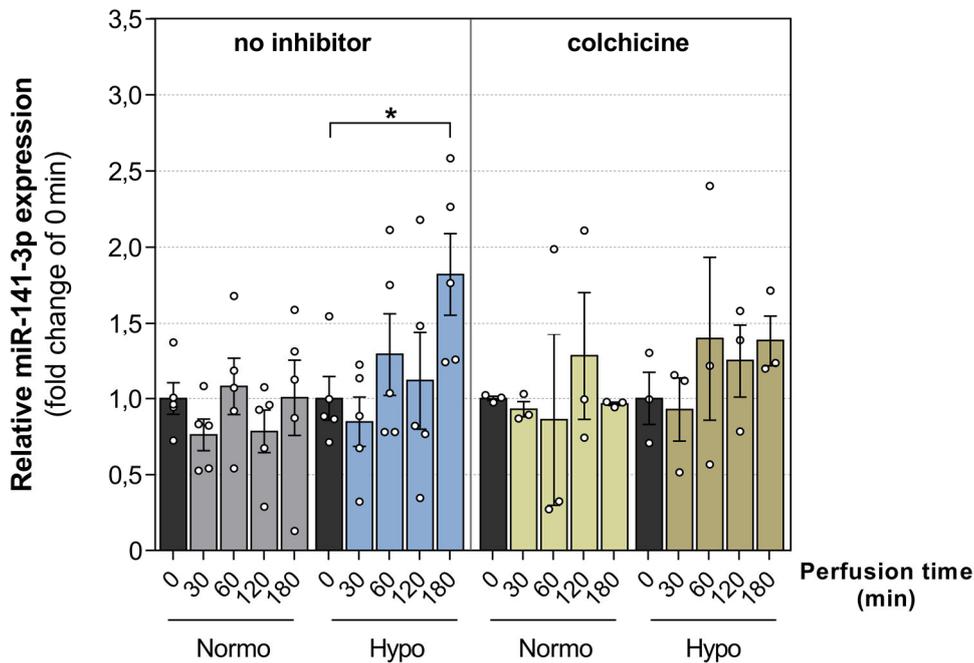

Figure 3.17 Analysis of miR-141-3p levels by hypoosmolarity in presence of colchicine. Rat livers were perfused with normo- (305 mosm/L) or hypoosmotic (225 mosm/L) medium for 0-180 min. Colchicine (500 nM) was added to the perfusate as indicated. After initialization of perfusion, liver lobes were dissected at the indicated time points, RNA was isolated and miR-141-3p expression was quantified by miQPCR. Data represent the relative expression of miR-141-3p as percentage to the preperfusion state (0 min). miRNA levels were median normalized by scaling the samples to their median value [226]. Statistical analysis was carried out by two-way ANOVA (n=3, data are shown as average \pm SEM with * $p < 0.05$).

Addition of colchicine to the perfusate resulted in lower miR-141-3p expression levels under hypoosmolarity compared to hypoosmotic perfusion without the addition of colchicine. Under hypoosmotic condition the addition of colchicine to the perfusate induced a moderate miR-141-upregulation to 1.38-fold (± 0.16) after 180 min of perfusion compared to normoosmotic control (Fig. 3.17 right). No significant changes in miR-141-3p levels were observed in comparison with rat liver perfusion in absence of colchicine (Fig. 3.17 left). Altogether, these data indicate that the addition of colchicine to the perfusate prevented miR-141-3p increase in perfused rat liver under hypoosmolarity.

4. Discussion

Liver cells face constant challenges to their cellular volume either through extracellular osmolarity or changes in intracellular solute content. These volume perturbations are counteracted by activation of specific membrane transporters and/or metabolic processes, which result in net solute loss or gain. Osmosensing and osmosignaling pathways are known which couple cellular volume to gene expression, proliferation, and apoptosis. However, the role of miRNAs regarding liver cell environment and the downstream osmosignaling pathways, which are coupled to hypoosmotic exposure, is largely unknown. This study aimed to analyze miRNA and mRNA expression differences during hypoosmotic exposure in perfused rat liver, and to identify miRNAs which are involved in the osmosignaling pathway. Based on bioinformatic approaches, 249 osmosensitive mRNAs were identified to be putatively targeted by a single miRNA, miR-141-3p. Using quantitative PCR analysis, miR-141-3p was found to be significantly upregulated under hypoosmotic condition in perfused rat liver, while selected putative target mRNAs were significantly downregulated. This effect was also observed in isolated primary rat hepatocytes, where individual mRNAs were also found to be downregulated after miR-141-3p upregulation. A luciferase reporter-based assay was performed to validate *Cdk8* mRNA, which is involved in critical cellular processes, such as transcription or cell cycle, as a direct target of miR-141-3p [238]. The role of miR-141-3p in the osmosignaling pathway under hypoosmolarity was investigated by inhibitor perfusion studies. This approach revealed that miR-141-3p levels were significantly affected by Erk and p38^{MAPK} inhibition. Inhibition of Erk and p38^{MAPK} led to a significant downregulation of miR-141-3p under hypoosmotic condition. In addition, miR-141-3p and *Cdk8* mRNA levels were analyzed after partial hepatectomy (PHx), a condition exposing liver cells to persistent mechanical stress due to hyperperfusion. Primary rat hepatocytes were subjected to mechanical stimuli, to assess their potential role in proliferation and liver regeneration, since PHx also subjects the liver cells to increased mechanical forces due to the increasing blood volume passing through the blood vessels [234].

4.1 Hypoosmolarity leads to differential miRNA and mRNA levels

Microarray chip analysis of miRNA and mRNA levels of hypoosmotic perfused rat livers revealed differentially expressed miRNAs and mRNAs after 180 min of perfusion. Only 9 (1.2%) of 728 miRNAs were found to be significantly downregulated, and 22 (3.0%) miRNAs being significantly upregulated. Thus, the number of differentially expressed miRNAs under hypoosmolarity compared to the normoosmotic controls seems to trigger very specific changes in miRNA levels. Several upregulated miRNAs found by microarray analysis, such as miR-338-5p, miR-18a-5p, and miR-155-3p were already identified by other studies to promote

4. Discussion

cell proliferation and/or inhibit apoptosis [239]. For example, miR-18a-5p was found to promote proliferation, migration, and invasion by targeting *fructose-bisphosphatase 1 (FBP1)* in liver cells [240], whereas Tang *et al.* discovered that miR-155-3p promotes proliferation by suppressing *f-box and wd repeat domain containing 7 (FBXW7)* expression in the liver [241]. These results underline the effects facilitated by hypoosmotic exposure to liver cells, since cell swelling was shown to be correlative with enhanced cell proliferation [68,82].

Gene chip analysis of hypoosmotic perfused rat liver revealed 609 (2.8%) significantly downregulated and 534 (2.5%) significantly upregulated mRNA compared to normoosmotic control. Interestingly, mRNA encoding for heat-shock protein 70 (*Hsp70*), which is upregulated in cells exposed to hyperosmolarity [242,243], was also found to be significantly elevated under hypoosmotic condition in the present microarray analysis. Under hyperosmolarity, *Hsp70* gene expression is activated by the denaturation of proteins, which is induced by hyperthermia [244]. Enrichment of *Hsp70* mRNA is known to be accompanied by many types of stress, fulfilling the role of stabilizing native protein structures and prevent harmful accumulation of denatured proteins. Kurz *et al.* also observed higher *Hsp70* mRNA levels in primary rat hepatocytes under hypoosmotic exposure when a heat shock was applied to the cells compared to normoosmotic control [245]. In agreement with previous data by Kurz *et al.*, enriched *Hsp70* mRNA levels in hypoosmotic perfused rat livers compare well to those found in primary rat hepatocytes exposed to a heat shock followed by hypoosmotic condition [245]. These findings may indicate that increased *Hsp70* mRNA levels under hypoosmolarity assist in the prevention of aggregation and misfolding of proteins.

Moreover, *heat-shock transcription factor 1 (Hsf1)* is induced by hypertonic shock with the same intensity which can be found by the activation via application of a heat shock [121]. *Hsf1* is a stress-induced transcription factor, that binds to the promoter region of heat-shock proteins (HSPs) to regulate their transcription [246]. Microarray analysis of perfused rat liver exposed to hypoosmolarity revealed *Hsf1* and *Hsf2* were both significantly downregulated after 180 min of hypoosmotic exposure compared to normoosmotic control (Fig. 3.2). Thus, hypoosmolarity led to an opposite regulation of *Hsf1* and *Hsf2*. Hypoosmotic and hyperosmotic exposure represent two opposing physical forces - which when applied to the living cell - can result in different physiological responses and functions, including different signaling pathways (Fig. 1.2). Therefore, it is conceivable that the upregulation of *Hsf1* and *Hsf2* mRNA is required only for the cellular response to hyperosmolarity, while other genes may be major players in the cellular response to hypoosmolarity.

4. Discussion

In the recent extension of this work, a potential player in nutrient and osmosignaling pathways, *transcription factor EB (Tfeb)* was significantly downregulated under hypoosmotic conditions compared to normoosmotic controls (Bardeck *et al.* [247]). *Tfeb* is involved in the function and biogenesis of the endo-lysosomal compartment, which includes membrane trafficking and autophagy [248,249]. During autophagy, which is a catabolic process, *Tfeb* mRNA levels are increased [249]. However, cell swelling is considered as an anabolic signal, leading to the inhibition of proteolysis [16,24–26], which might be the reason for decreased *Tfeb* mRNA levels.

Overall, microarray analysis of differentially expressed mRNAs revealed that the effect of hypoosmolarity on perfused rat livers only affected a small fraction of the liver transcriptome. These changes point towards the specificity of the swelling signal, which were also observed in previous studies performed by Warskulat *et al.* [250]. They discovered that hyperosmotic exposure led to an increase of the mRNA levels of *tyrosine aminotransferase (Tat)* and *phosphoenolpyruvate carboxykinase (Pepck)*, whereas hypoosmotic exposure to H4IIE rat hepatoma cells decreased their mRNA levels by about 40%. These data are in accordance with our microarray chip analysis of hypoosmotic perfused rat livers, where *Tat* and *Pepck* mRNA levels were also decreased by similar amounts. This effect may be explained by the increased stimulation of glycolysis and glycogen synthesis, which are both sensitive to cell swelling [15]. As a main control point for the regulation of gluconeogenesis, *Pepck* catalyzes the formation of phosphoenolpyruvate from oxaloacetate and the expression of the *Pepck* gene can also be affected by insulin and glucagon [251,252]. Both hormones affect the cellular hydration level, allowing the hypothesis that *Pepck* mRNA levels are directly affected by the cellular hydration level. Long-term effects of hypoosmotic exposure to rat livers regarding the mRNA level have already been described in the past. For instance, enriched mRNA levels for *tubulin* [23,237], *β -actin* [35], *ornithine decarboxylase* [253], and *c-jun* [254] were found in rat liver perfusion and primary rat hepatocytes in response to hypoosmolarity. Our microarray analysis also found *actin beta (Actb)* and *ornithine decarboxylase (Odc1)* at increased levels. Hypoosmotic exposure to liver cells leads to alterations of the cellular shape and can alter cytoskeletal rearrangements, thus leading to changes in the expression patterns of proteins like *Actb*, which are required for the cytoskeletal structure.

In the next step, downregulated mRNAs were investigated for possible binding sites for miRNAs which were upregulated in rat livers following perfusion with hypoosmotic medium. Remarkably, *TargetScan* and *miRWalk* revealed that out of 609 downregulated mRNAs, 249 (41%) mRNAs were putatively targeted by miR-141-3p (Fig. 3.3 A). The GO enrichment analysis revealed the involvement of miR-141-3p target gene candidates in various cellular

4. Discussion

processes, including the regulation of cell cycle, metabolic processes, and the biosynthesis of cellular macromolecules (Fig. 3.3 B). These findings are in accordance with effects found in cells affected by hypoosmotic exposure (e.g. enhanced proliferation and altered metabolism), thus making miR-141-3p an interesting target for further investigation.

miR-141-3p belongs to the miR-200 family which is composed of five highly conserved miRNAs: miR-200a/200b/200c, miR-141, and miR-429 [255]. It is established, that miR-141-3p is implicated in different types of oncogenesis, but its function in the liver is still not clarified [256–258]. The miR-200 family members are mainly recognized as tumor suppressors, but depending on the cellular context the biological functions of the miR-200 family are subject to change and may also exert tumor promoting effects [259]. However, these long-term effects were not investigated in this thesis. miR-200 family members are associated with the formation of cancer stem cells and the regulation of epithelial-to-mesenchymal transition (EMT), in which cells gain migratory and invasive properties resulting in the transition to mesenchymal stem cells [260–262]. miR-141-3p inhibits cell proliferation and invasion by targeting mitogen-activated protein kinase 4 (*MAP4K4*) [263], but in contrast may also act as an oncogene in ovarian and colon cancers [264,265]. These findings suggest that miR-141-3p has various roles which may depend on its specific target in different cell types or tissues.

4.2 Downregulation of downstream target genes of miR-141-3p

Hepatic miR-141-3p levels were significantly upregulated after 180 min of hypoosmotic perfusion compared to normoosmotic control (Fig. 3.4). Upregulation of miR-141-3p after 180 min of rat liver perfusion is an experimental model for mimicking long-term effects of hypoosmotic exposure, since liver cells regain their original cell volume within minutes with the help of RVD mechanisms.

To elaborate the role and function of miR-141-3p, predicted target gene candidates which play a role in proliferation, cell cycle progression, and cellular metabolism, were selected for further analyses. As shown in Figure 3.5, after 180 min of hypoosmotic perfusion, all selected target gene candidates were significantly or tendentially downregulated on the mRNA level.

Among the downregulated mRNAs, *Nfat5*, also known as a tonicity-responsive enhancer-binding protein, is an important transcription factor involved in the maintenance of cellular homeostasis against hypertonic and hyperosmotic environments [266]. Under hyperosmotic stress the amount and nuclear translocation of *Nfat5* is increased, to accumulate organic osmolytes and restore cell homeostasis [267–269]. *Nfat5* is responsible for the expression of a variety of osmoprotective genes, such as ion transporters, aldose reductase,

4. Discussion

and heat shock protein 70 [270]. It was also shown by Zhu *et al.* that *Nfat5* triggers autophagy by the activation of autophagy related protein 5 (*Atg5*) [271]. As presented in Figure 3.5, *Nfat5* mRNA levels were significantly downregulated after 180 min of hypoosmotic exposure. In contrast, Bounedjah *et al.* identified upregulation of *Nfat5* mRNA under hyperosmotic exposure [272].

In this thesis, the opposing regulation of *Nfat5* mRNA under hypoosmolarity could be a direct result of miR-141-3p upregulation. Therefore, miR-141-3p may be in-part responsible for the restoration of cellular homeostasis by directly binding to *Nfat5* mRNA. However, it cannot be excluded that additional mechanisms may also affect *Nfat5* levels, since *Nfat5* activity is regulated through phosphorylation of signal molecules like Fyn [273], p38^{MAPK}, and protein kinase A [274,275]. Furthermore, activation of *Nfat5* and downstream activation of autophagy is not required during hypoosmolarity which is an anabolic signal, thus leading to the inhibition of proteolysis [27].

Zmpste24 is another putative miR-141-3p target gene candidate downregulated under hypoosmotic condition in perfused rat livers. This gene encodes for a zinc metallopeptidase that is involved in the two step post-translational proteolytic cleavage of prelamin A to form mature lamin A, which is required for the structure of the cell nucleus membrane [276]. Additionally, in human, *ZMPSTE24* is identified as a direct target of miR-141-3p [277]. Here, *ZMPSTE24* mRNA levels were decreased, while miR-141-3p was found to be upregulated during senescence in mesenchymal stem cells. Decreased levels of *ZMPSTE24* mRNA led to an upregulation of prelamin A mRNA in mesenchymal stem cells. These findings lead to the assumption, that by targeting *Zmpste24*, miR-141-3p can directly affect the formation of lamin A which is required during the S-phase of cell division [278].

Another confirmed target of miR-141-3p is *cell division cycle protein 25A (Cdc25a)* mRNA. As a dual-specificity protein phosphatase, it is responsible for the progression from G1 to the S phase of the cell cycle [279]. *Cdc25a* removes the inhibitory phosphorylation in cyclin-dependent kinases (CDKs) such as cyclin-dependent kinase 6 (Cdk6), cyclin-dependent kinase 4 (Cdk4), and cyclin-dependent kinase 2 (Cdk2). Qiu *et al.* demonstrated that high miR-141-3p levels decreased the expression of Cdc25a on the protein level, which results in the arresting of cells at G1 phase without triggering cell apoptosis [279]. In hypoosmotic rat liver perfusion and primary rat hepatocytes exposed to hypoosmotic media, *Cdc25a* mRNA levels were significantly downregulated compared to normoosmotic controls. As an important player in cell cycle progression, the activity of Cdc25A on the protein level must be timely and precisely regulated throughout the whole cell cycle. Previous studies confirmed multiple

4. Discussion

mechanisms behind the regulation of *Cdc25A* expression at the transcriptional [280,281], translational [282,283], and post-translational level [284]. Interestingly, Qiu *et al.* observed that miR-141-3p increased the expression of *CDC25A* on the mRNA level and also decreased its expression on the protein level, showing that miR-141-3p affects gene expression on both transcriptional and post-transcriptional level [285]. Again, by targeting *Cdk25a*, miR-141-3p may be in-part responsible for processes which include cell proliferation in the liver. Furthermore, cyclin-dependent kinase 8, a subunit of the regulatory Cdk module of the transcriptional Mediator complex [286] that couples enhancer-binding transcriptional activators to RNA polymerase II for the initiation of transcription [238], was identified as a putative target of miR-141-3p. Cyclin-dependent kinases are involved in critical cellular processes such as transcription or cell cycle. *Cdk8*, unlike better-known members of the Cdk family (e.g. *cyclin-dependent kinase 1* [287] or *cyclin-dependent kinase 2* [288]), is not required for cell cycle progression [286,289] and instead co-regulates several transcription factors, such as *Wnt/β-catenin* [290], serum response network [291], *TGFβ/SMAD* [292], and *NFκB* [293]. *Cdk8* is amplified or overexpressed in many types of cancers, including colon [290], breast [289,294,295], pancreatic [296], and prostate cancer [297]. Many mechanisms of positive regulation of transcription such as the regulation of RNA-polymerase II by Cdk8 have been elucidated [291,298–300] with fewer known mechanisms of negative regulation by Cdk8 in mammalian cells [301]. As a co-regulator of above-mentioned transcription factors, downregulation of *Cdk8* mRNA under hypoosmolarity may play a role in cell growth, cell differentiation, and/or apoptosis. Furthermore, Cdk8 is linked to lipid and glucose metabolism, as well as to the regulation of the cellular response to the depletion of nutrients [301–303]. Knockdown experiments conducted in mammalian cells revealed that Cdk8 kinase activity upregulates the expression of glycolytic enzymes [304]. These findings underline the role of Cdk8 as an oncogene and for stem cell maintenance [305,306], since metabolic changes can be responsible for the alteration in gene expression or the proteome [307]. Additionally, metabolic changes may drive cell differentiation and cancer, whereas cancer cells are heavily dependent on glycolysis [308,309] and differentiated, non-proliferating cells redirect metabolites towards oxidative phosphorylation [310].

Collectively, these data indicate that miR-141-3p may assist in the modulation of various processes, which may contribute to proliferation, cell differentiation, and cellular metabolism, mediated via its downstream target genes.

4.3 Hypoosmolarity leads to miR-141-3p upregulation in primary rat hepatocytes and restoration of cytoskeleton

Hepatocytes constitute the majority of the liver volume and retain most of their functions after isolation and restoration of the cell cytoskeleton [311–313]. To identify a potential source behind enriched miR-141-3p levels under hypoosmolarity, isolated primary rat hepatocytes were exposed to hypoosmotic medium *in vitro*. To measure the extent of swelling, which cells endure during hypoosmotic exposure, microscopical images were taken after cells were exposed to hypoosmotic medium for 5 min and 3 h (Fig. 3.6). Isolated primary rat hepatocytes showed an increased cell nucleus accompanied by an upregulation of miR-141-3p level after 24 h of hypoosmotic exposure compared to normoosmotic controls. Since ambient osmolarity changes were achieved by the addition of raffinose, enrichment of miR-141-3p levels can be explained by changes in osmolarity or cell volume, and not by alterations of extracellular Na⁺ or Cl⁻ ion concentrations. However, the hypoosmotically-induced effect of miR-141-3p upregulation showed a delay of more than 20 h compared to the observed effect in perfused rat livers. Primary rat hepatocytes retain specific hepatocyte properties close to their physiological level, although the *in vivo* state cannot be maintained for long. Discrepancies in the observed effects may also be explained by the missing biological cell matrix of *in vitro* primary rat hepatocytes, which is still preserved in the perfusion experiments. Interaction of different neighboring cell types may be crucial for relevant short-scale signaling transductions. Furthermore, isolated primary rat hepatocytes lack an intact microtubule network, which is required for the antiproteolytic effect of cell swelling [23,314]. Thus, anti-proteolytic effects cannot be shown in isolated primary rat hepatocytes [315], which are characterized by a disintegrated microtubule network [23,69,117]. Taken altogether, these factors may be responsible for a more timely *in vivo* signaling towards miR-141-3p, which can not be shown *in vitro* at early time points. Quantitative analysis of previous selected target gene candidates showed a significant downregulation for *Slc39a10*, *Dsty*, *Rab30*, *Cdc25a*, *Dmx11*, and *Nfat5* on the mRNA level. *Cdk8*, *Zmpste24*, *Camsap1*, *Msantd2*, *Eml4*, *Luc7l3*, and *Prmt1* tended to decrease at the mRNA level (Fig. 3.7), thus, exposure of isolated primary rat hepatocytes to hypoosmolarity showed similar results compared to hypoosmotic liver perfusions. Taken together, these data suggests that hepatocytes, which make up to 70% of the liver cell population, may be the primary source for miR-141-3p expression levels in the liver under hypoosmotic condition. These findings solidify the idea that miR-141-3p might influence the expression of various processes, including cell proliferation, cell differentiation, and cell cycle progression via its downstream target genes in the liver. This leads to the assumption, that upregulation of miR-141-3p may be a direct response to hypoosmotic exposure and ultimately

contributes to the modulation of transcriptional events which are interlinked with liver cell swelling [68,82].

4.4 miR-141-3p transfection leads to downregulation of target gene candidates

To further investigate the effects of miR-141-3p on its downstream target genes, mRNA levels of previous selected target gene candidates were analyzed in response to miR-141-3p overexpression in isolated primary rat hepatocytes (Fig. 3.9). After 24 h of miR-141-3p mimic transfection, several genes tended to decrease at the mRNA level, including *Cdk8*, *Dstyk*, *Camsap1*, *Eml4* and *Nfat5*. However, *Cdk8* and *Eml4* were significantly decreased at the mRNA level after 48 h of miR-141-3p mimic transfection, while *Luc7l3* and *Pmrt1* showed tendentially decreased mRNA levels (Fig. 3.10).

Of note, isolated primary rat hepatocytes are extracted from their natural cell matrix, which might be a decisive prerequisite for the interplay of miR-141-3p and its target genes. The moderately affected mRNA levels raise the hypothesis that besides enriched miR-141-3p levels certain additional mechanisms may control the mRNA levels of selected target gene candidates *in vitro*. However, more work is necessary to further investigate the mediating effects of miR-141-3p on its target genes in response to cellular stimuli.

To provide the evidence for a direct interaction between miR-141-3p and *Cdk8* mRNA, a luciferase reporter gene assay was conducted. As shown in Figure 3.11, two possible binding motifs were determined in the 3'UTR of *Cdk8* mRNA, strengthening the idea that miR-141-3p may be in-part responsible for the downregulation of *Cdk8*. Moreover, miR-141-3p mimic transfection inhibited the expression of luciferase by binding directly to the 3'UTR of *Cdk8* mRNA (Fig. 3.12), certifying the miRNA-MRE interaction of *Cdk8* mRNA and miR-141-3p. These findings are in line with bioinformatic analysis conducted with *TargetScan* software and *RNA22* algorithm which revealed two binding sites for miR-141-3p in the sequence of *Cdk8* 3'UTR. Collectively, the luciferase reporter assay provided evidence that *Cdk8* 3'UTR can be confirmed as a direct target of miR-141-3p.

4.5 Role of miR-141-3p and *Cdk8* in liver regeneration

To investigate a possible role of miR-141-3p and its downstream target gene *Cdk8* in liver regeneration, liver tissue from rats recovering from PHx was analyzed. In normal adult livers, hepatocyte proliferation is rarely seen, as most hepatocytes are in the G0 phase of the cell cycle [316,317]. However, after PHx approximately 95% of hepatic cells rapidly re-enter the cell cycle [114]. Quantitative PCR analysis of rat liver tissue revealed that miR-141-3p levels start to increase after 24 h, reaching a significance 36 h after PHx (Fig. 3.13 A). In rats, the

4. Discussion

rate of DNA synthesis in hepatocytes is increased after 12 h and peaks around 24 h after PHx [114]. These findings raise the possibility that miR-141-3p upregulation is tied to the proliferative phase of hepatocytes during rat liver regeneration, since transiently upregulated miR-141-3p levels can be observed during and shortly after (i.e. 24 h and 36 h) hepatocyte proliferation. Simultaneously, *Cdk8* mRNA levels show a decrease after 24 h, reaching a significant downregulation after 6, 10 and 14 days after PHx (Fig. 3.13 B). As a direct target of miR-141-3p, downregulation of *Cdk8* mRNA may be a result of increased miR-141-3p levels. These findings point towards an involvement of miR-141-3p and *Cdk8* in rat liver regeneration. Ko *et al.* also reported the participation of *Cdk8* in the initial steps of liver regeneration in zebrafish [318]. Repression of Cdk8 protein led to an enhanced Notch signaling which induced differentiation of liver progenitor cells (LPC) into hepatocytes [318]. However, future studies are required to elucidate the detailed mechanism behind the upregulation of miR-141-3p and regulation of *Cdk8* in liver regeneration. Furthermore, several other mRNA candidates responsible for proliferation and cell differentiation like *Cdc25a*, *Camsap1*, and *Eml4* mRNA remain to be investigated.

The signals that determine the size of the liver during liver regeneration and the termination phase are still poorly understood, but a few mechanisms like the inhibition of specific growth factor and cytokine-mediated pathways are able to regulate organ size [114]. Suppressors of cytokine signaling (SOCS) are important regulators that prevent tyrosine phosphorylation of signal transducer and activator of transcription (STAT) proteins [319–321]. *Interleukin 6 (IL-6)* signaling has been shown to directly affect the upregulation of *SOCS3*, which is coupled with the subsequent downregulation of phosphorylated *STAT3*, ultimately terminating *IL-6* signaling [322]. Additionally, SOCS proteins also provide an important mechanism to prevent uncontrolled cytokine signaling [323]. Furthermore, *transforming growth factor β (TGF β)* is upregulated during liver regeneration [324]. *TGF β* activity can be assessed by SMAD activation, which is located downstream of *TGF β* . Interestingly, transcriptional activation of SMAD is regulated via phosphorylation by *Cdk8* which subsequently promotes the recruitment of yes associated transcriptional regulator (YAP) to the phosphorylated linker sites [325,326]. Phosphorylation of SMAD by *Cdk8* provides an important counterbalance to *TGF β* signaling [325,327]. Once liver regeneration is terminated, SMAD levels decrease, while the liver is returning to a quiescent state [328]. Therefore, it is conceivable that downregulation of *Cdk8* mRNA via miR-141-3p may be interlinked to processes which determine the termination phase during liver regeneration.

Precise signaling during the termination phase is important, since uncontrolled initiation of cell cycles and uncontrolled proliferation are characteristics of cancer cells. Especially during liver

4. Discussion

regeneration, excessive cell proliferation can lead to HCC [329]. In the past, miR-141-3p and the miR-200 family have been demonstrated to be dysregulated in pancreatic ductal adenocarcinoma cells, with a direct enhancement effect on cell proliferation [330]. These effects are in part mediated through miR-141-3p downstream target genes, such as *zinc finger e-box binding homeobox 1 (ZEB1)* and *zinc finger e-box binding homeobox 2 (ZEB2)*, both well-known for their EMT regulatory effects [331,332]. Thus, miR-141-3p upregulation and its target downregulation of *Cdk8* mRNA could potentially play an additional role during the termination phase of liver regeneration to prevent the potential emergence of HCC during uncontrolled cell cycle progression. These results further consolidate earlier findings, where upregulation of miR-141-3p in hypoosmotic perfused rat liver was observed after 180 min, possible functioning as a time delayed 'signal' to cease cell proliferation. This hypothesis can be further substantiated by the fact, that during hypoosmolarity enhanced cell proliferation in rat liver perfusion can be observed [68,250,333,334].

4.6 Regulation of miR-141-3p is sensitive to mechanical stimulation

During liver regeneration and/or hypoosmotic cell swelling the membrane of affected liver cells endure both compression and stretching. As mentioned before, these mechanical stimuli can be sensed by integrins and transmitted into downstream signaling pathways [69,91,116]. An increase in hepatocellular volume leads to an integrin-dependent EGFR and Erk1/-2 activation in hepatocytes, triggering a proliferative response [68,335,336]. In the past, K⁺-selective ion channels were discovered which are both activated by membrane stretch and by cell swelling induced by hypoosmotic exposure [337]. As stated earlier, activation of K⁺ ion channels in rat liver results in RVD [31–35]. Primary rat hepatocytes, which were subjected to a lateral stretch by roughly 30%, showed a significant increase in miR-141-3p expression levels after 1 h. After 2 h and 3 h, miR-141-3p expression levels are slowly declining, which was accompanied by reshaping of the cells back to their initial size and form. Thus, upregulation of miR-141-3p may be linked to a mechanical stimulus which is probably sensed and transmitted by integrins via a controlled mechanism called mechanotransduction.

Interestingly, Cheng *et al.* discovered that compression along an axis (e.g. horizontal axis) can inhibit cell growth and induce a programmed cell death in tumor spheroids [338]. However, this effect was highly dependent on the cell density. Regions of high cell density are affected by high compressive stress resulting in apoptosis, whereas regions of low cell density allowed proliferation [338]. Because isolated primary rat hepatocytes are highly confluent on the silicone stretch chambers, these findings may further lead to the assumption that miR-141-3p is in-part responsible for anti-proliferative effects in hepatocytes.

4. Discussion

Furthermore, *Cdk8* mRNA levels showed a tendency towards decrease 2 h and 3 h after cells were subjected to stretching. However, for an early regulatory effect additional mechanisms may be implicated, since a lateral stretch might impair mechanically gated ion channels. Affected ion channels could be responsible for co-regulation of transcriptional activation for certain mRNAs. Additionally, interaction and communication with neighboring cells via soluble factors and gap junctions may also influence transcription of *Cdk8*. Dolega *et al.* observed that global compression of tumor spheroids decreased the volume of on a larger scale than osmotic compression of single cells [339]. It still remains unclear if cells sense osmotic compression through the same pathways which are implicated through solid stress, including stretch-activated ion channels or involvement of the cytoskeleton and cell-matrix adhesions [339,340].

4.7 Src, Erk, and p38^{MAPK} signal miR-141-3p regulation

Hypoosmotic cell swelling is sensed by the integrin system, resulting in a subsequent activation of c-Src kinase and downstream targets like Erk and p38^{MAPK} [91,92]. To further elucidate the role and the required signal transductions in response to miR-141-3p upregulation in the osmosignaling pathway, inhibitor perfusion studies were conducted. Through the addition of specific Src-, Erk, and p38^{MAPK} inhibitors to rat liver perfusions, hypoosmotic-induced upregulation of miR-141-3p was prevented (Fig. 3.16). Furthermore, inhibition of Erk and p38^{MAPK} signaling resulted in a significant downregulation of miR-141-3p after 120 min of rat liver perfusion, indicating that miR-141-3p may be a feedback mechanism downstream of Src, Erk and p38^{MAPK}. As Src, Erk, and p38^{MAPK} are well-known downstream effectors of the signaling pathways induced by hypoosmolarity [91,92,341,342], this is the first study indicating that miR-141-3p may be directly involved in cellular mechanisms as a response to hypoosmotic condition, mechanical stimulation, and cell swelling.

Addition of colchicine to the perfusate also resulted in the prevention of a significant upregulation of miR-141-3p by hypoosmolarity, although a tendency towards upregulation after 180 min was observed (Fig. 3.17). Colchicine is known to induce depolymerization of the microtubule network by preventing the assembly of α -tubulin leading to an inhibition of mitosis [24,343]. Microtubules are a major component of the cytoskeleton of hepatocytes and play an established role in their physiology [344–346]. The organization of microtubules and the spindle apparatus are mediated via p38^{MAPK} and play an active role in cellular hydration, since microtubules are able to bind different proteins, including ionic channels responsible for the transport of Ca²⁺ ions [347–350]. Furthermore, swelling-mediated effects of hypoosmotic exposure require an intact cytoskeleton and the physiological interaction between extracellular matrix proteins and the integrin system [68,351,352]. Thus, inhibition of microtubules by

4. Discussion

depolymerization, resulting in the prevention of miR-141-3p upregulation, may indicate the involvement of miR-141-3p in the osmosignaling pathway triggered by hypoosmotic-induced swelling. Additionally, Wang *et al.* reported that *circular kelch like ECH associated protein 1* (*circKEAP1*) is a direct target of miR-141-3p. Overexpression of *circKEAP1* in human A549 cells led to decreased levels of cell mitosis and lower percentages of proliferation as also seen by the application of colchicine [353,354], further supporting the idea that miR-141-3p is involved in cell proliferation control of the liver.

4.8 Conclusion

In conclusion, the insights gained in the present study identified miR-141-3p as an osmosensitive miRNA which plays a potential role as a modulator in liver cell swelling and proliferation. It is proposed that hypoosmotic conditions lead to an upregulation of miR-141-3p, most likely controlled by $\alpha_5\beta_1$ -integrin-, Src-, Erk-, and p38^{MAPK} signaling. As a result, mRNA levels of various genes involved in metabolic processes, macromolecular biosynthesis, and cell cycle progression such as *Cdk8*, *Cdc25a*, *Zmpste24*, and *Nfat5* are directly affected and coherently downregulated. Rat livers subjected to PHx also exhibited elevated miR-141-3p levels, placing miR-141-3p and its target gene *Cdk8* into a regulative signaling network of the regenerative liver, although tension-influenced mechanotransduction seems to differ from signaling events induced by hypoosmotic conditions.

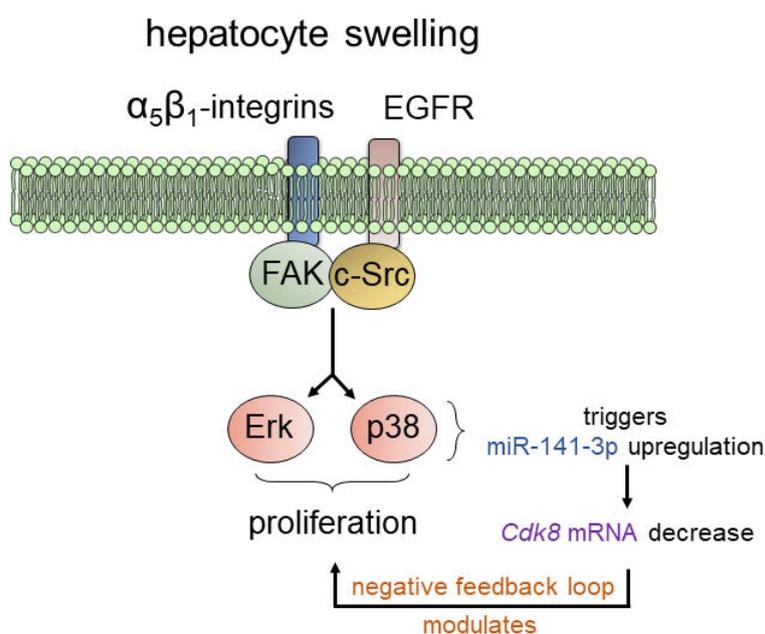

Figure 4.1 Proposed model for the feedback mechanism controlled by miR-141-3p. During hypoosmotic exposure and liver regeneration, cell swelling and deformation is sensed by transmembrane adhesion receptor $\alpha_5\beta_1$ -integrins through mechanical stimuli. Following activation, they mediate the Src-, Erk-, and p38^{MAPK}-kinase activation which leads to proliferation. Triggered by this event, upregulation of miR-141-3p results in decreased mRNA levels of miR-141-3p target genes, including *Cdk8* mRNA. As a hypothesis of this work, miR-141-3p could be responsible to modulate cell proliferation in the liver, e.g. preventing excessive hepatocyte growth during liver repair.

Furthermore, miR-141-3p overexpression was triggered by a mechanical stimulus, leading to the assumption that mechanosensors such as $\alpha_5\beta_1$ -integrins may be in-part responsible for the signaling to mediate miR-141-3p expression. Yet, more work is required to fully understand the role of miR-141-3p in the liver and its potential contribution to osmosensing, osmosignaling as well as cell proliferation during liver regeneration. Future studies must take into

4. Discussion

consideration that miR-141-3p has been described to fulfill diverse functions depending on specific targets in different cell types or tissues.

6. Acknowledgements

I would like to express my gratitude and my sincere thanks to Professor Dr. Dieter Häussinger and Dr. David Schöler for the opportunity to conduct my PhD thesis in the Clinic for Gastroenterology, Hepatology and Infectious Diseases in Düsseldorf. Furthermore, I would also like to thank Professor Dr. Stephan vom Dahl for taking over the role as PhD advisor.

I would also like to thank Professor Dr. Holger Gohlke for providing his time and his interest in my research topic and for reviewing my PhD thesis.

A special thanks to Dr. Martha Paluschinski for her support, her expertise, and her charming manners since my first workday.

Another special thanks to Dr. Claus Kordes for proof-reading my work and his helpful suggestions, explanations, and constructive criticism over the years.

I would also like to thank my colleagues at the Experimental Hepatology for their helpful support in the laboratory and the pleasant working atmosphere. It has been a pleasure to work with you in such a friendly and welcoming environment.

Last but not least, I would like to thank my parents, my family, my girlfriend, and my friends for their support throughout the entire period of my doctoral thesis.

9. List of Publications and Scientific Presentations

Publication:

Nils Bardeck, Martha Paluschinski, Mirco Castoldi, Claus Kordes, Boris Görg, Jan Stindt, Tom Luedde, Stephan vom Dahl, Dieter Häussinger, David Schöler

“Swelling-induced upregulation of miR-141-3p inhibits hepatocyte proliferation.”

JHEP Reports - 2022, in press

Nils Bardeck, Martha Paluschinski, Mirco Castoldi, Tom Luedde, Dieter Häussinger, Stephan vom Dahl, David Schöler

„Liver cell swelling leads to upregulation of miR-141-3p in perfused rat liver and primary rat hepatocytes.”

Zeitschrift für Gastroenterologie – January 2021, 59. Edition, Page 9

(Thieme, Stuttgart, Deutschland)

Poster presentation:

“Liver cell swelling leads to upregulation of miR-141-3p in perfused rat liver and primary rat hepatocytes.”

37. Annual meeting GASL (29th – 30th January 2021)

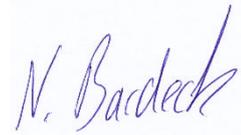

10. Curriculum vitae

07/2018 until 06/2021	Research Ph.D. student Heinrich-Heine-Universität, Düsseldorf
10/2017 until 12/2017	Research Assistant Ruhr-Universität Bochum, Bochum
08/2012 until 07/2017	Study: Biology Ruhr-Universität Bochum, Bochum Degree: Master of Science
08/2011 until 07/2012	Study: Bio- and nanotechnology Fachhochschule Südwestfalen, Iserlohn
08/2009 until 07/2011	Training as biological-technical assistant Hans Böckler Berufskolleg, Marl Degree: Biological-technical assistant
08/1999 until 07/2009	Gymnasium Borbeck, Essen Degree: High school diploma

Eidesstattliche Versicherung

Ich, Herr Nils Bardeck, versichere an Eides statt, dass die vorliegende Dissertation von mir selbstständig und ohne unzulässige fremde Hilfe unter Beachtung der „Grundsätze zur Sicherung guter wissenschaftlicher Praxis an der Heinrich-Heine-Universität Düsseldorf“ erstellt worden ist.

Düsseldorf, der 19. Dezember 2022
